

Lecture 1: Overview and the Night Sky at a Glance

...

Learning Objectives and Overview

By the end of this course, students will be able to:

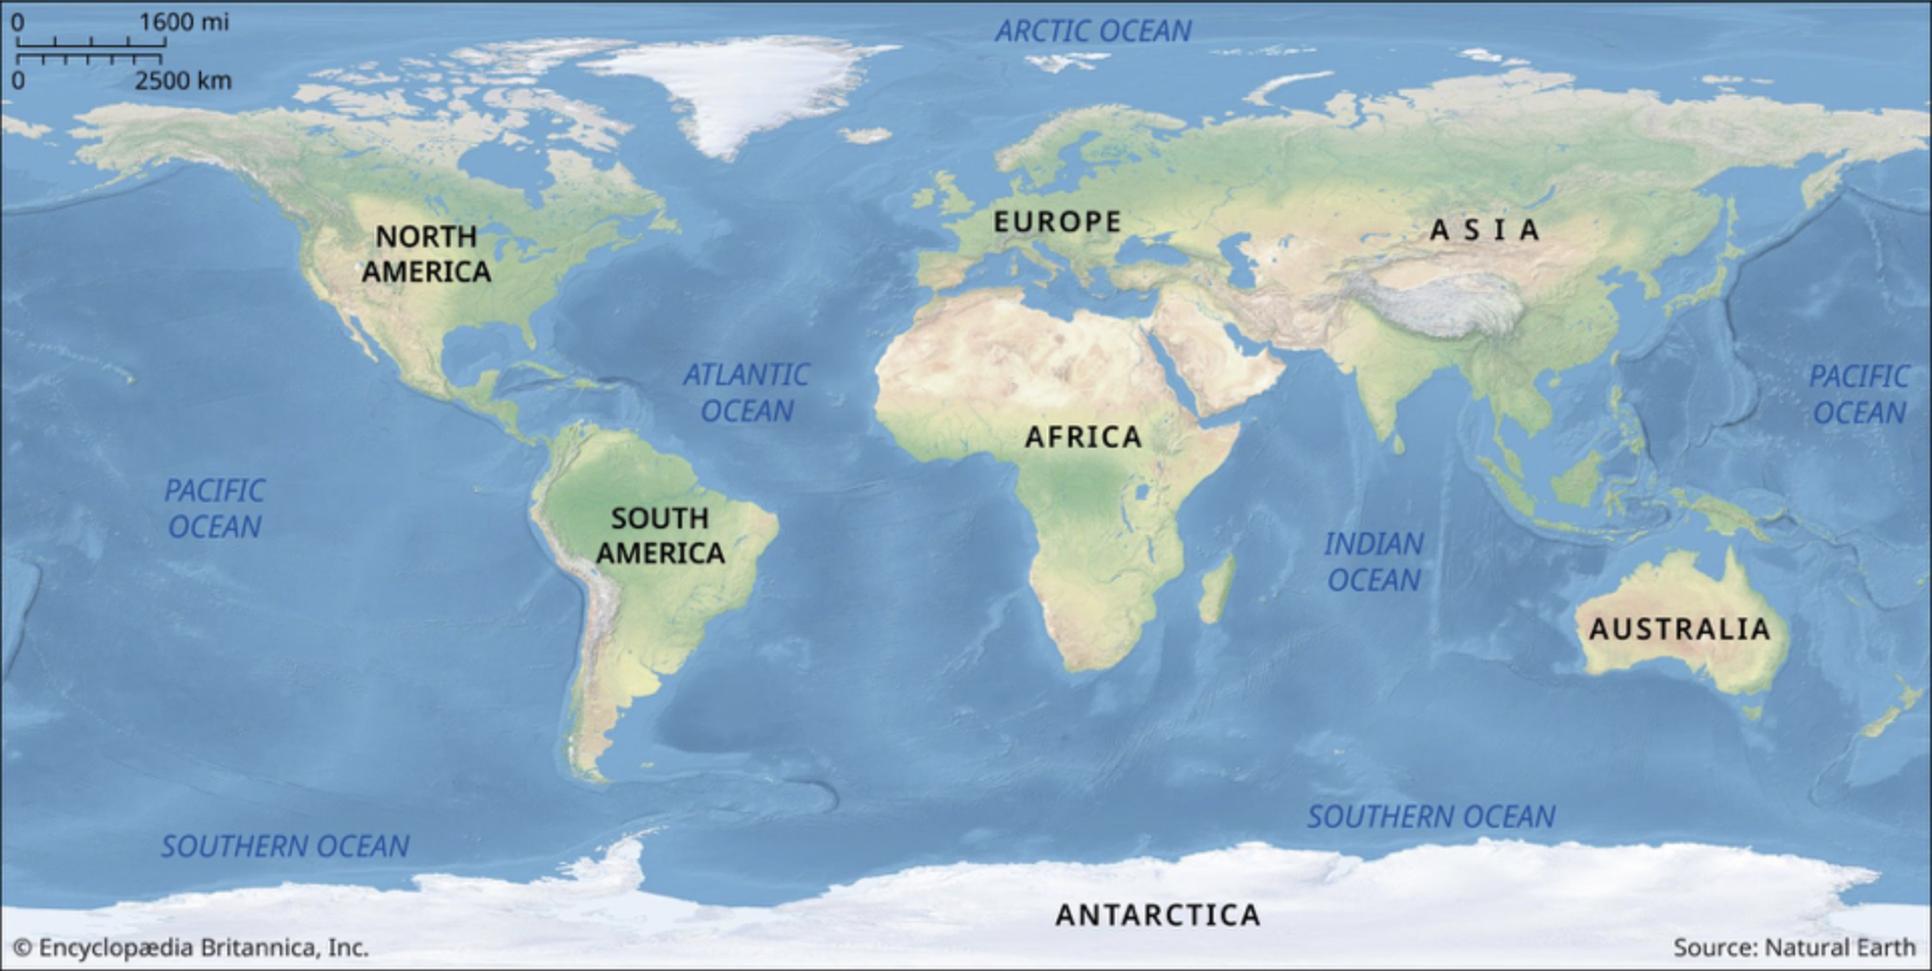

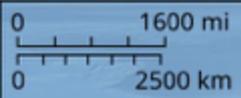

...identify major stars and constellations in the night sky, recount the life-cycle of a star from the Main Sequence to supernova, and distinguish between White Dwarfs, Neutron Stars, and Black Holes.

...describe the basic components of an optical telescope, explain the major differences between optical, infrared, and UV astronomy, describe why X-ray and gamma ray telescopes operate differently from OIR and UV telescopes.

...describe the basic components of a radio antenna, explain how radio interferometers work, and list the astrophysical sources of radio waves.

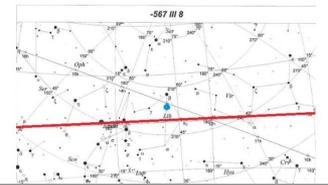

...describe the components of a galaxy (disk, bulge, ISM, halo, CGM), define cosmology, how it is studied (redshift, CMB, 21 cm cosmology, simulations, FRBs), explain how distance, redshift, and time are related within general relativity, and understand how the presence of dark matter and dark energy affect our picture of the Universe.

...list some of the major questions in astronomy today and refer to resources to continue exploring astronomy within and around Pasadena.

Milestones in Modern Astronomy

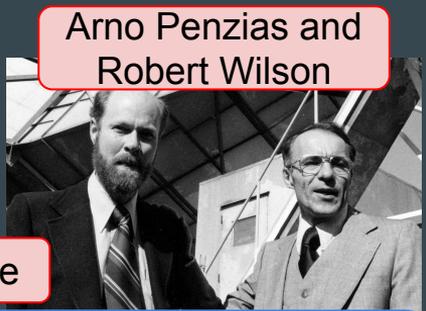

Isaac Newton

Henrietta Swan Leavitt

Edwin Hubble

Arno Penzias and Robert Wilson

1608 – Invention of the Telescope

1687 – Newton's Laws of Gravity

1918 - Galaxy Center

1920s - Hubble's Law of Universal Expansion & Einstein's Theory of General Relativity

1543 – Heliocentric Solar System

1609 – Kepler's Laws of Elliptical Motion

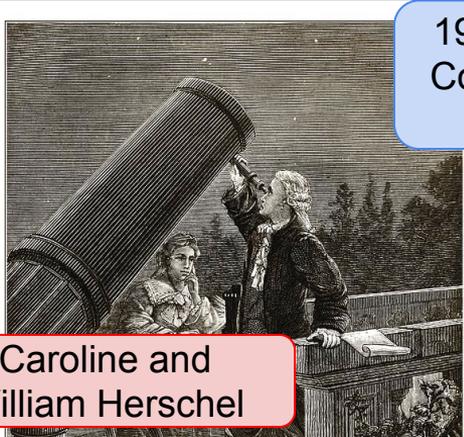

1800 - Discovery of IR Radiation

1964 - Cosmic Microwave Background

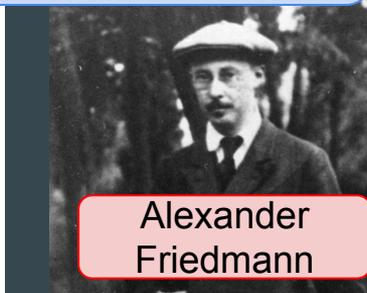

1908 - Distance/Period Correlation for Cepheid Variable Stars

Galileo Galilei

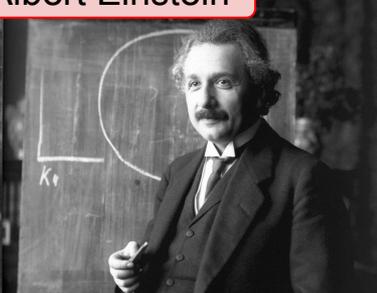

Caroline and William Herschel

Alexander Friedmann

Albert Einstein

Distance Scales

AU=Astronomical Unit

ly=light-year

pc=parsec

8 kpc = 1.6 billion AU

2.5 million ly = 765 kpc

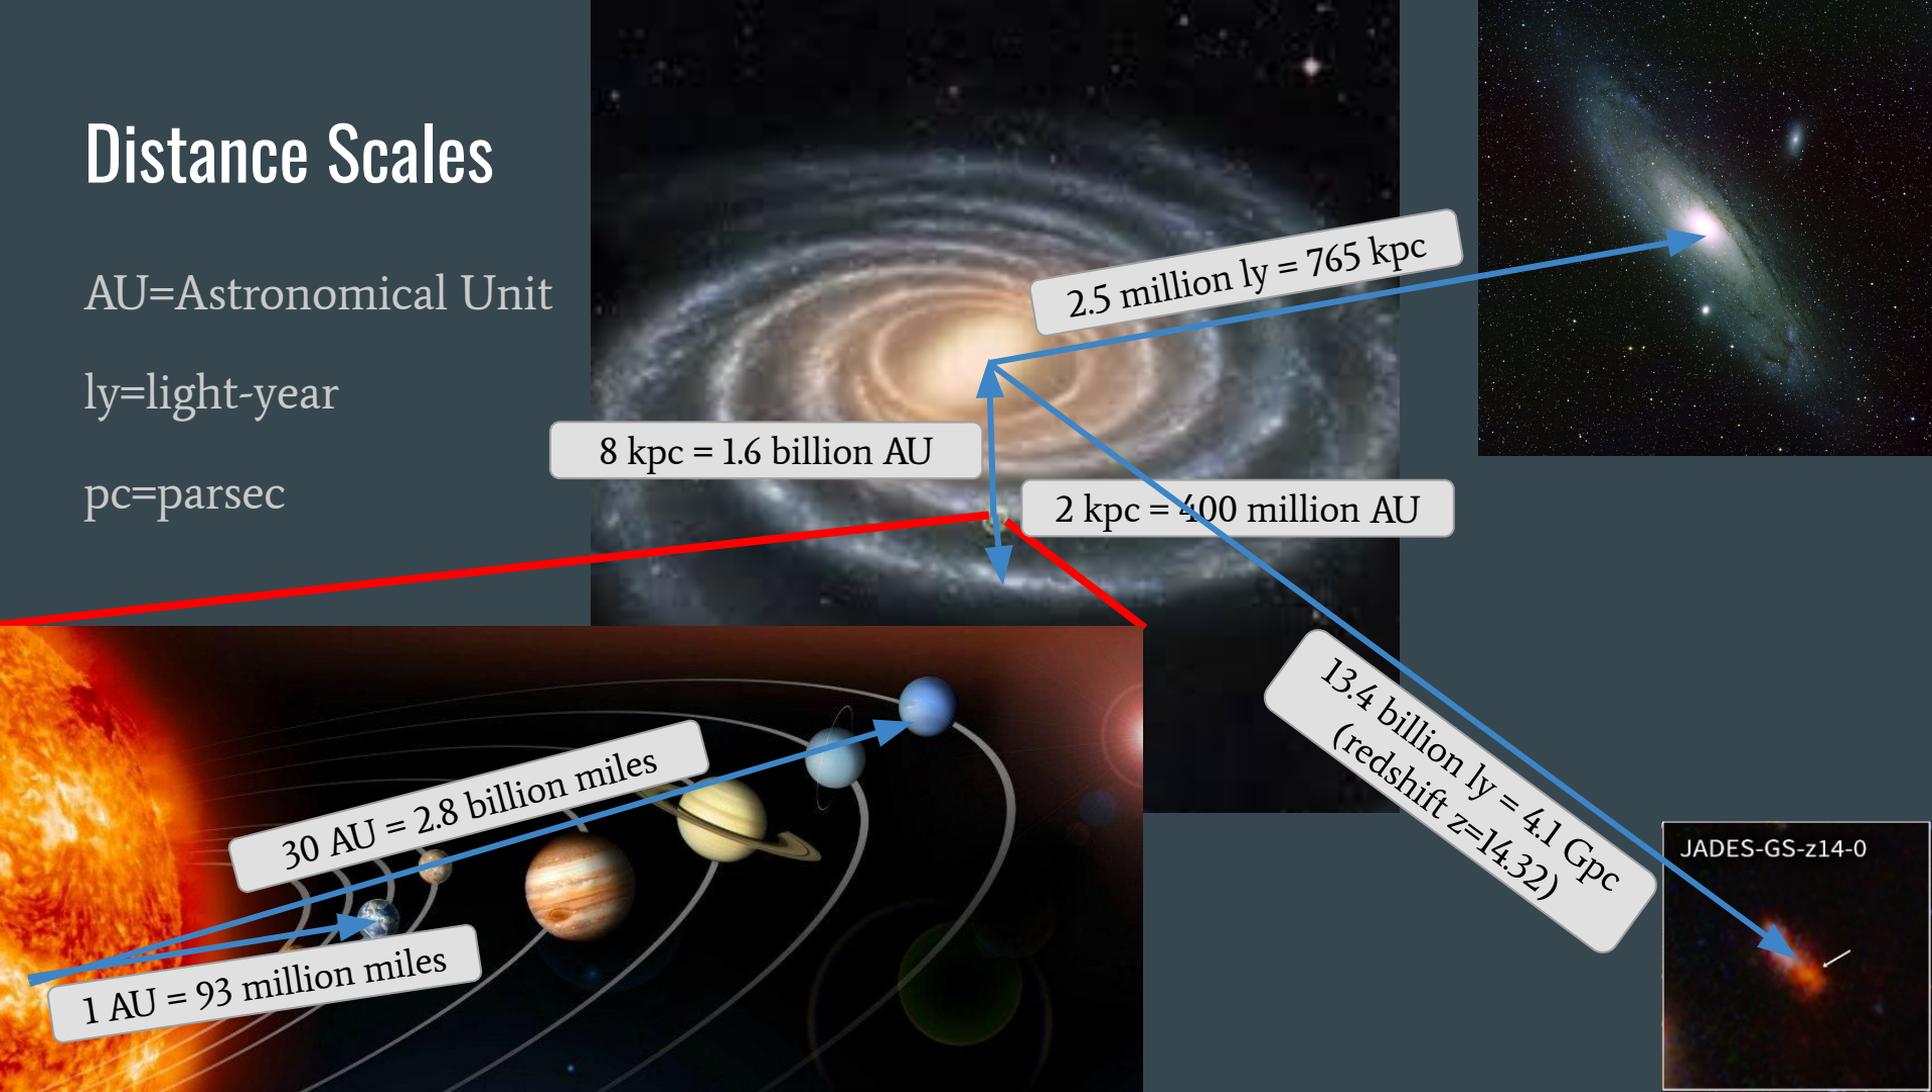

2 kpc = 400 million AU

13.4 billion ly = 4.1 Gpc
(redshift $z=14.32$)

30 AU = 2.8 billion miles

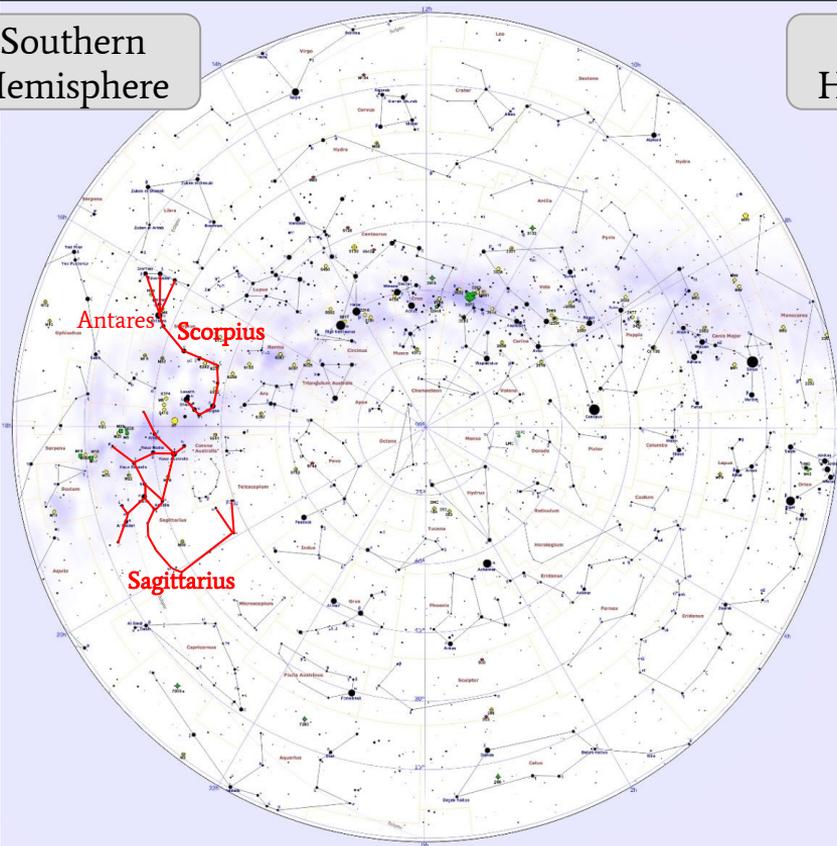

1 AU = 93 million miles

Northern Hemisphere

Navigating with Constellations and Asterisms: Winter in Pasadena

Southern Hemisphere

Northern Hemisphere

Celestial Coordinates

Sidereal Time: time measured relative to field stars instead of the Sun

1 Sidereal Day = 23 hours 56 minutes

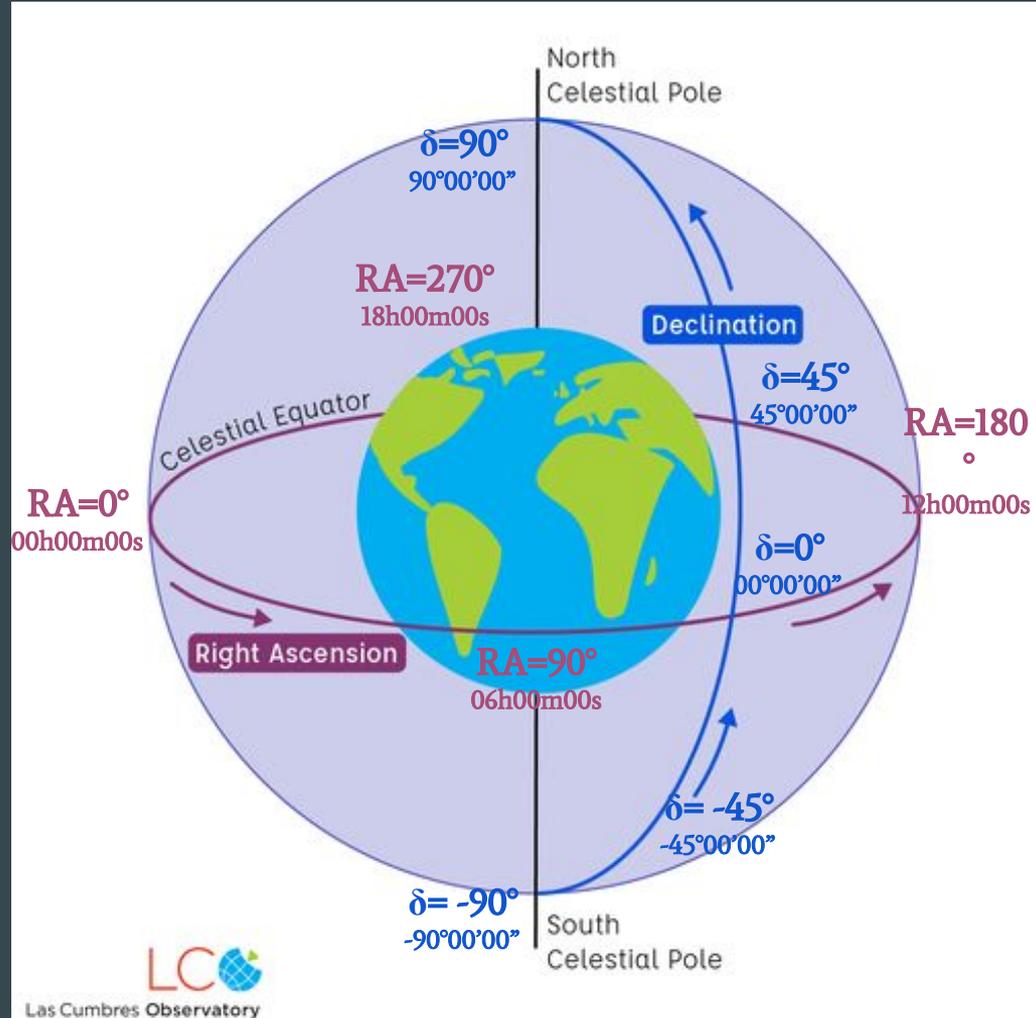

Centered on Earth and aligned with Equator and Poles:

- **Right Ascension (RA;** Celestial Longitude)
- **Declination** (Celestial Latitude)

RA can be specified in **degrees (0 - 360)** or **hours (0 - 24)**

$$\text{RA}[\text{degrees}] = 15 \times \text{RA}[\text{hours}]$$

Local Sidereal Time (LST): current RA overhead at the observer's location

At-Home Astronomy: Online Star Maps

Stellarium: <https://stellarium-web.org/>

Make Your Own Star Wheel (*Sky & Telescope*):
<https://stellarium-web.org/>

Aladin: <https://aladin.cds.unistra.fr/AladinLite/>

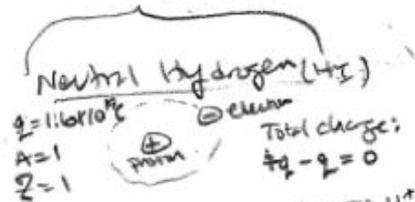

Pan-Starrs (Northern Sky Survey):
<https://pslimages.stsci.edu/cgi-bin/pslcutouts>

SkyMapper (Southern Sky Survey):
<https://skymapper.anu.edu.au/image-cutout/>

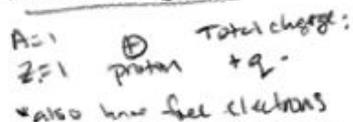

Interstellar Medium (ISM) - gas & dust between stars in the Galaxy

~70% of ISM is Hydrogen

Ionized Hydrogen (H^{II} , H^+)

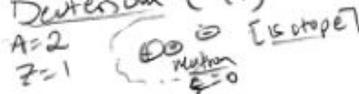

$N_{SM} \sim 10^{22}$ particles per cubic cm (cm^{-3})

Molecular Hydrogen (H_2)

molecular clouds

Deuterium (2H)

~28% of ISM is Helium

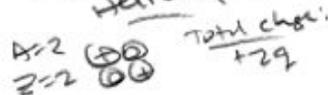

Neutral Helium (He)

Singly-ionized Helium (He^+)

Doubly-ionized Helium (He^{2+})

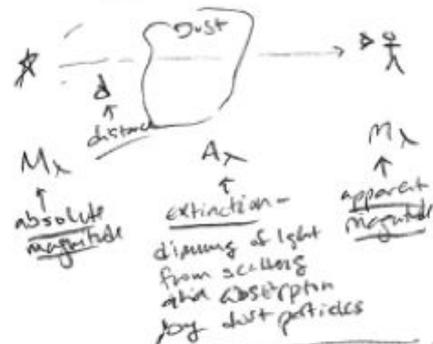

~1.5% of ISM are Metals - any element with $Z > 2$ (heavier than Helium)

~0.5% of ISM is Dust

- silicates, carbon molecules, hydrocarbons, graphite

↳ Carbon (C): $A=6$

$$M_x = M_x + 5 \log \left(\frac{d}{10} \right) - 5 + A_x$$

1.21

Energy - "ability to move or change matter in some way"

- energy is always conserved: $E_{\text{initial}} = E_{\text{final}}$

Kinetic Energy

$m = \text{mass}$
 $v = \text{velocity}$

$$E_{\text{kinetic}} = \frac{1}{2} m |\vec{v}|^2 > 0$$

Boltzmann Dist.
 $f(v) = \left(\frac{m}{2\pi kT}\right)^{3/2} \exp\left(-\frac{mv^2}{2kT}\right)$

Thermal Energy

Ideal gas law: $PV = NkT$

$N = \# \text{ particles}$
 $k = 1.38 \times 10^{-23} \text{ J/K}$
 $T = \text{temperature (K)}$

$$E_{\text{thermal}} = \frac{3}{2} NkT > 0$$

Potential Energy - stored energy that can change to another form

Gravitational Potential Energy

r $\left\{ \begin{array}{l} \vec{F}_g = \text{force due to gravity (g = 9.81 m/s}^2) \\ E_{\text{grav}} = mgr < 0 \end{array} \right. \rho_0 \text{ near } R$

Newton's Gravitational Constant

$$G = 6.67 \times 10^{-11} \frac{\text{m}^3}{\text{kg s}^2}$$

$F_{\text{grav}} = \frac{GMm}{r^2}$
 $E_{\text{grav}} = -\frac{GMm}{r} < 0$
for 2 masses

$E_{\text{grav}} = -\frac{3}{5} \frac{GM^2}{R} < 0$
for extended object

free-fall time scale $t_{\text{ff}} = \sqrt{\frac{3\pi}{32G\rho_0}}$

Total Energy

$$E_{\text{tot}} = E_{\text{kinetic}} + E_{\text{grav}}$$

$< 0 \rightarrow \text{bound}$
 $> 0 \rightarrow \text{unbound}$

Virial Theorem: $2E_{\text{kinetic}} + E_{\text{grav}} \approx 0$ (equilibrium)

How does a cloud of gas collapse into a star?

initial density: $\rho_0 = \frac{M}{\frac{4}{3}\pi R^3}$
 $R = \left(\frac{3M}{4\pi\rho_0}\right)^{1/3}$

System will collapse if $2E_{\text{kinetic}} + E_{\text{grav}} < 0$
 $2\left(\frac{3MkT}{4\pi}\right) < \frac{3GM^2}{R}$
 $\frac{1 \cdot R}{G} \left(\frac{kT}{m}\right) < M \Rightarrow \frac{10}{9} \left(\frac{4}{3}\pi\right)^{1/3} \left(\frac{kT}{Gm}\right) < M^{2/3}$

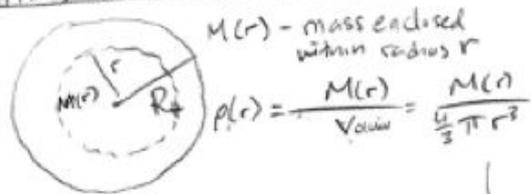

Jean's criteria

$$M_J \equiv \left(\frac{1}{3\pi}\right) \left(\frac{10kT}{9Gm}\right)^{3/2} < M$$

$$R_J \equiv \sqrt{\frac{15kT}{4\pi G \rho_0}} < R$$

1.3

Equations of Stellar Structure:

① Hydrostatic Equilibrium
balance of gravity and pressure:

$$\frac{dP}{dr} = -\frac{GM(r)\rho}{r^2} \rightarrow \text{star is only supported if pressure is higher at center of the star}$$

② Mass Conservation
 $\frac{dM}{dr} = 4\pi r^2 \rho(r)$

for constant density:

$$\frac{dM}{dr} = 4\pi r^2 \rho$$

$$\rho dM = M = \int_0^{R_*} 4\pi r^2 \rho dr$$

$$M = \frac{4}{3}\pi R_*^3 \rho$$

③ Pressure Equation of state - tells us how gas is composed and behaves

- Ideal gas - gas w/ negligible volume, similar sized particles & no interaction between particles.

$$P = \frac{N}{V} kT = \frac{\rho kT}{\mu m_H} \text{ velocity}$$

for any other gas: $P = \frac{1}{3} \int_0^\infty n p v dp$

n = density \rightarrow k = momentum

radiation pressure - pressure exerted by photons in thermal equilibrium

$$P = \frac{1}{3} a T^4 \quad \text{where } a = 7.56 \times 10^{-16} \text{ J/m}^3 \text{K}^4$$

⑤ Radiative Transport - describes how energy is transported within the star

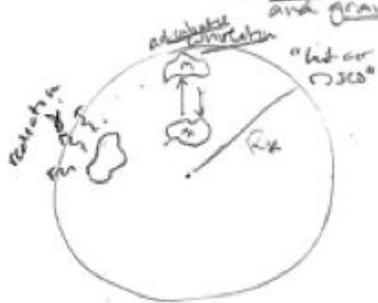

$$\frac{dT}{dr} = \left\{ \begin{array}{l} \frac{3}{4ac} \frac{\kappa_p}{T^3} \frac{L}{4\pi r^2} \quad \text{radiation} \\ \left(\frac{1}{\beta} - 1\right) \frac{4M}{k} \frac{GM}{r^2} \quad \text{adiabatic convection} \end{array} \right.$$

④ Luminosity Gradient -

- luminosity - power (energy produced per unit time)

$$\frac{dL}{dr} = 4\pi r^2 \rho(r) \epsilon(r)$$

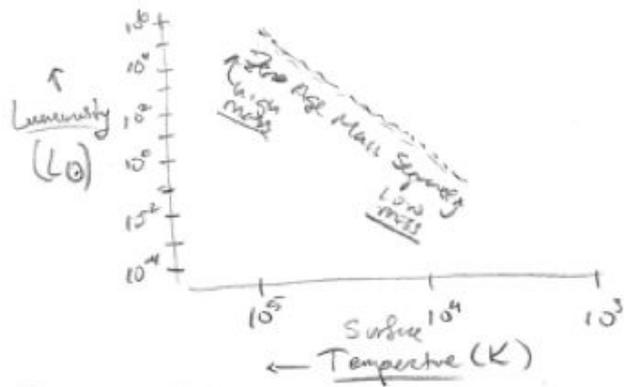

total power released per unit area by nuclear reactions and gravity

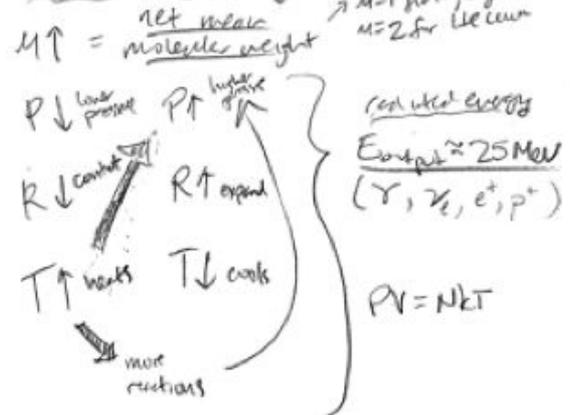

1.4

Stellar Evolution

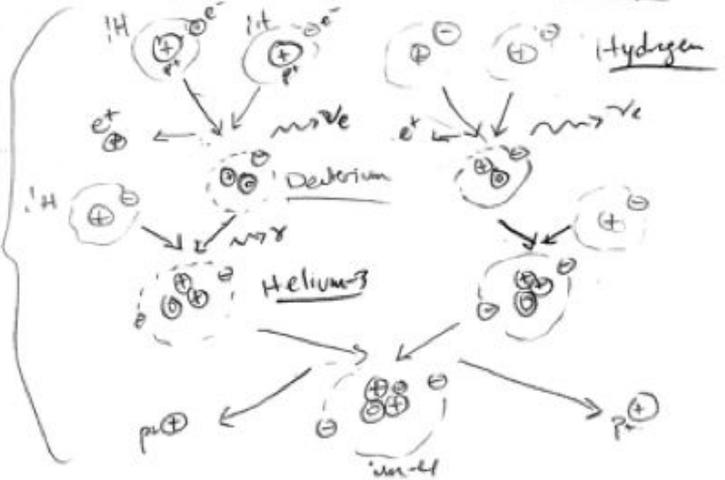

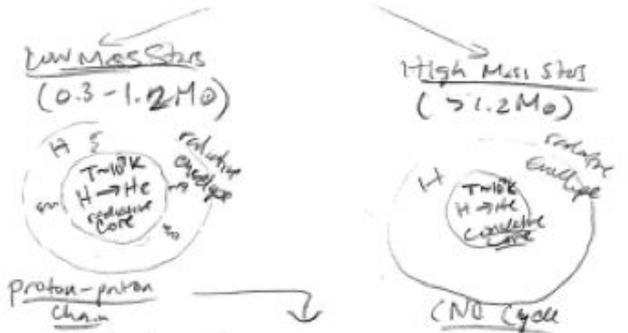

The Hertzsprung Russell Diagram

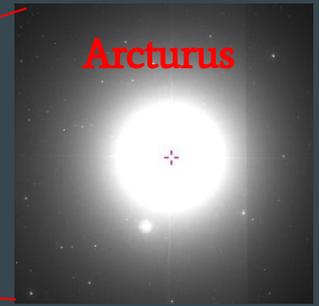

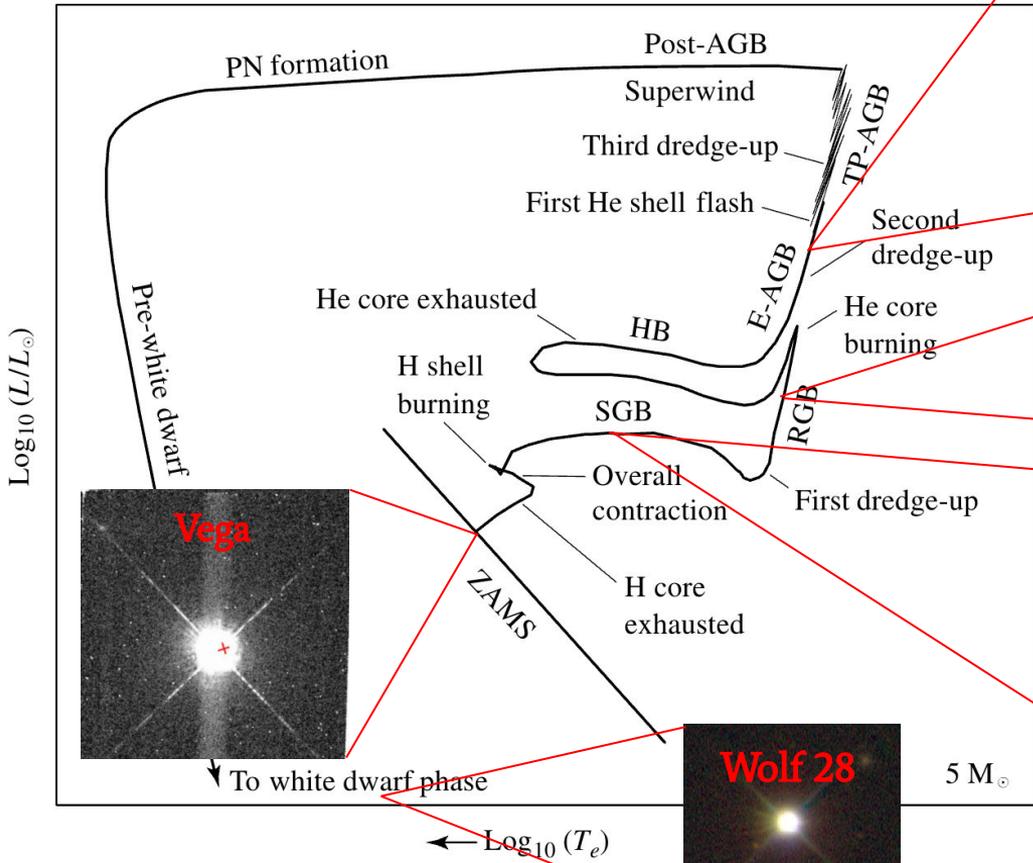

Feedback Stability

Main Sequence - Hydrogen burning to fuse into helium:

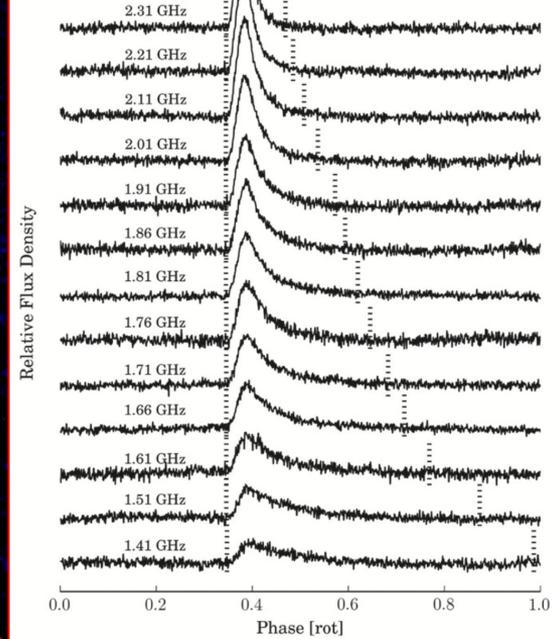

Black Hole

Sagittarius A*

Radio

Neutron Star

SGR 1745-29

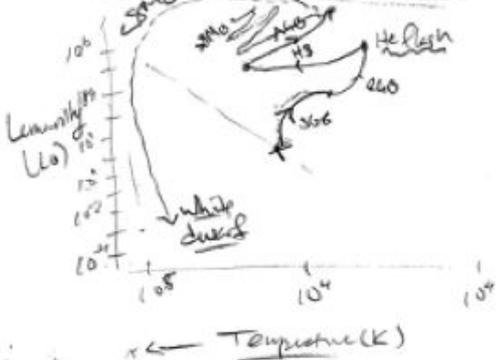

Radio

X-ray

1.5

Stellar Evolution

The Hertzsprung Russell Diagram

Sub-Giant Branch - after hydrogen finished to burn, needs to get to T and P to begin He fusion

Red Giant Branch
↓
Convective Mixing
↳ LT faster

core: contracts (R↓)
- heats (T↑)
releases gravitational energy + radiation

shell - continues hydrogen burning, deposits mass into core

Horizontal Branch - Helium burning, fusing to Carbon
↳ triple alpha process

envelope - Reddening process from core (P↑)
Luminosity increases (L↑)
expands (R↑) & T & P cools (T↓, P↓)

Asymptotic Giant Branch

Outer layers expand away
↓
core contracts
↓
β⁻ decay energy processes
white dwarf star

Continues burning cycle until core
↓
helium flash
core collapses → Helium shell flash

Same as Sub-giant/Red Giant

1.6)

White Dwarf Stars (for $M_* < 8M_\odot$)

- central star exposed gradually as envelope expands ($T_{\text{eff}} \uparrow \rightarrow$ blue)

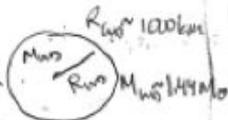

supported by e^- degeneracy pressure + quantum mechanical pressure

↳ Pauli exclusion principle - 2 electrons can't occupy the same energy state

↳ forces free electrons in core into higher energy states \rightarrow higher velocities \rightarrow "pressure"

$$P_e \propto \rho^{5/3}$$

↳ Chandrasekhar mass limit - maximum mass before e^- degeneracy pressure fails $\Rightarrow M_{\text{WD}} \sim 1.44M_\odot$

- for $M_* < 4M_\odot \rightarrow$ C, O white dwarf
- $4M_\odot < M_* < 8M_\odot \rightarrow$ O, Ne, Mg white dwarf

- mass loss accelerates (expanding envelope \rightarrow wind)

$$\dot{M} = dM/dt = 10^{-4} M_\odot/\text{yr}$$

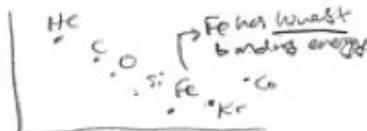

Neutron Stars & Black Holes (for $M_* > 8M_\odot$)

(Supergiant)

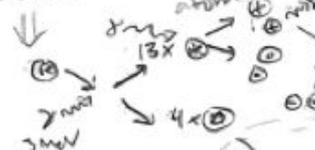

- continues burn until fuses iron (Fe) in core

- photodissociation binding energy

↳ $T > 10^{10} \text{K}$
 ↳ overcome pressure \rightarrow break down Fe atoms

energy required to break down Fe atoms into nucleons

$A =$ atomic mass #

- neutronization
 ↳ protons capture e^- and decay to neutrons

- core collapse

↳ outer layers infall under gravity

↳ "bounced" off central star

$M_{\text{core}} > 1.44M_\odot$

↳ collapses further into Black Hole

$M_{\text{core}} \leq 1.44M_\odot$

↳ neutron star

↳ core supported by neutron degeneracy pressure
 (since neutrons into high energy states)

$$P_n \propto \rho^{4/3}$$

↳ Chandrasekhar limit =

$$M_{\text{Ch}} = 1.4M_\odot$$

Think-Pair-Share

How would you classify a new star given its apparent magnitude?

Think-Pair-Share

How would you classify a new star given its apparent magnitude?

How might a binary companion star impact a star's evolution?

1.7 | BINARY STARS

	<u>Single</u>	<u>Binary</u>	<u>Triplet</u>
Sun-like stars	60%	30%	10%
O-type stars	6%	21%	73%

Most high mass stars are in orbit with other stars

Types of Binaries:

- Cataclysmic variables (CVs)

accretion disk

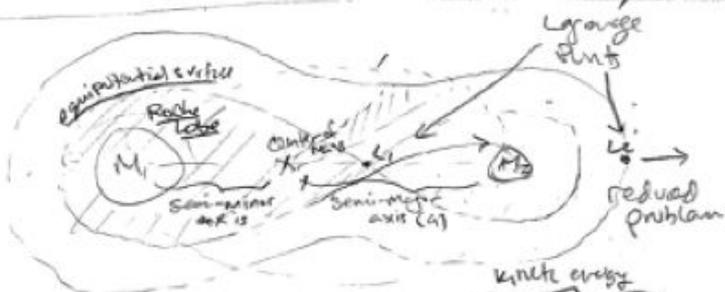

↳ Type Ia SNe - accrete mass until it exceeds Chandrasekhar limit

- X-ray Binaries: $M_{tot} = M_1 + M_2$

Center of MASS:

$$r_{CM} = \frac{M_1 r_1 + M_2 r_2}{M_1 + M_2}$$

total energy: $E = E_{kin} + E_{pot} = \frac{1}{2} M \dot{r}^2 + \frac{1}{2} M \omega^2 r^2 - \frac{GM_1 M_2}{r}$

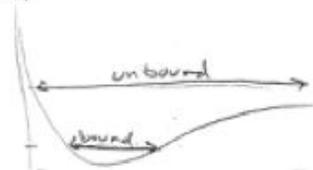

$= \frac{1}{2} M \dot{r}^2 + M \omega^2 r^2 - \frac{1}{2} M \omega^2 r^2 - \frac{GM_1 M_2}{r}$

effective kinetic energy K_{eff} : $\frac{1}{2} M \dot{r}^2$

effective potential energy U_{eff} : $U_{eff} = -\frac{1}{2} M \omega^2 r^2 - \frac{GM_1 M_2}{r}$

effective potential: $V_{eff} = \frac{U_{eff}}{M} = -\frac{1}{2} \omega^2 r^2 - \frac{G(M_1 + M_2)}{r}$

V_{eff}

Kepler's Laws

- Stars & Planets in bound systems move in elliptical orbits around the center of mass
- Area swept out by a radius vector is constant: $dA/dt = \text{constant}$
- Orbital period squared is proportional to the semi-major axis cubed: $T_{orb}^2 = \frac{4\pi^2}{G(M_1 + M_2)} a^3$

Questions, Comments, or Concerns?

Lecture 2: Electromagnetic Radiation from Infrared to Gamma Rays

...

Learning Objectives and Overview

By the end of this course, students will be able to:

...identify major stars and constellations in the night sky, recount the life-cycle of a star from the Main Sequence to supernova, and distinguish between White Dwarfs, Neutron Stars, and Black Holes.

...describe the basic components of an optical telescope, explain the major differences between optical, infrared, and UV astronomy, describe why X-ray and gamma ray telescopes operate differently from OIR and UV telescopes.

...describe the basic components of a radio antenna, explain how radio interferometers work, and list the astrophysical sources of radio waves.

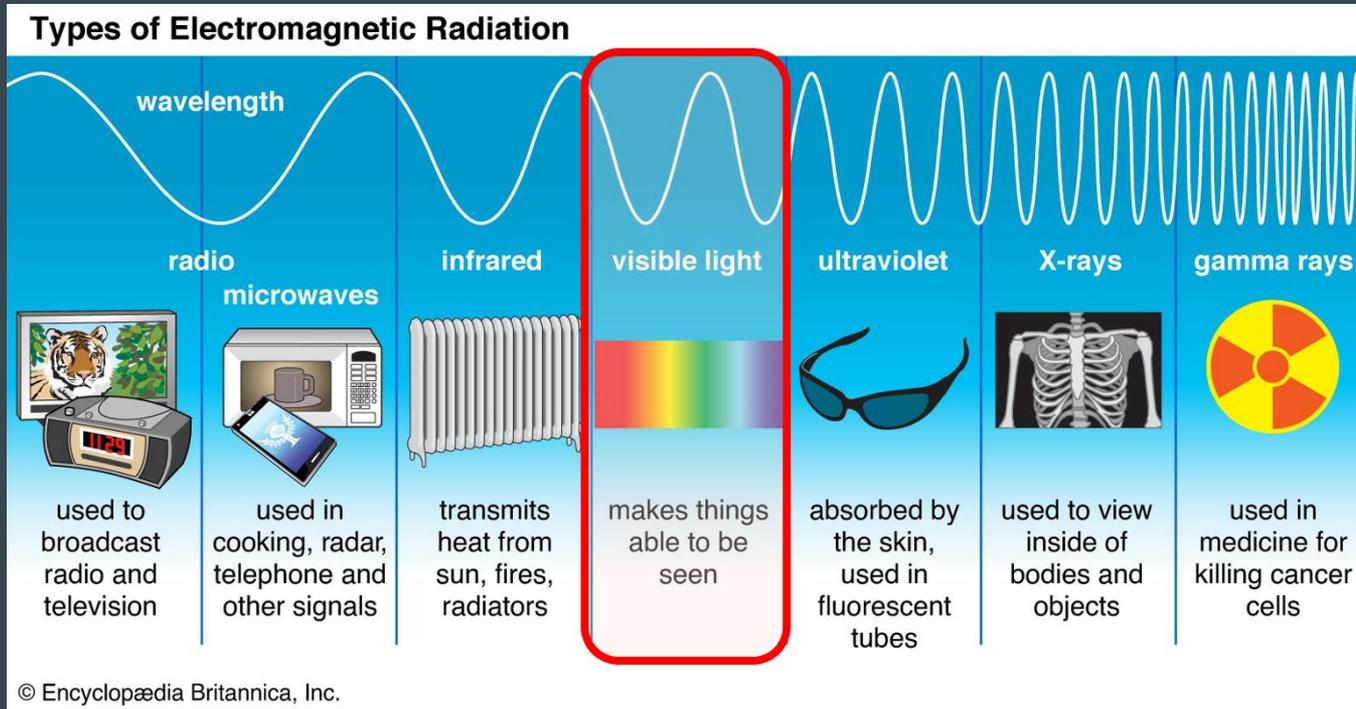

...describe the components of a galaxy (disk, bulge, ISM, halo, CGM), define cosmology, how it is studied (redshift, CMB, 21 cm cosmology, simulations, FRBs), explain how distance, redshift, and time are related within general relativity, and understand how the presence of dark matter and dark energy affect our picture of the Universe.

...list some of the major questions in astronomy today and refer to resources to continue exploring astronomy within and around Pasadena.

What is Light?

Light is **energy** that travels in **waves** carried by electric and magnetic fields

All waves have a wavelength and speed $c=671$ million miles per hour = 299 million meters per second

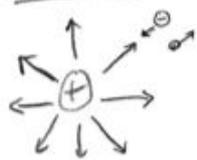

Light can also be defined as particles, **photons**, which are discrete **quanta** of electromagnetic fields

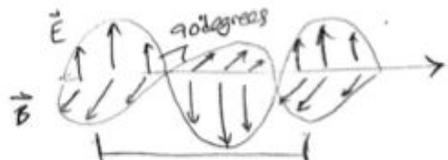

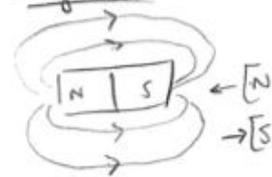

2.11

Electromagnetic Radiation (Light) -

Electric field

Magnetic field

Wavelength (λ) - distance between wave crests

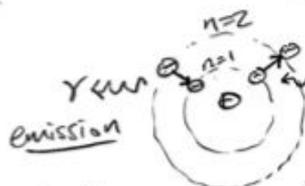

frequency (ν): $\nu = c/\lambda$

Energy: $E = h\nu = pc$
Planck's Constant

speed of light
 $c = 300 \text{ million meters/second}$

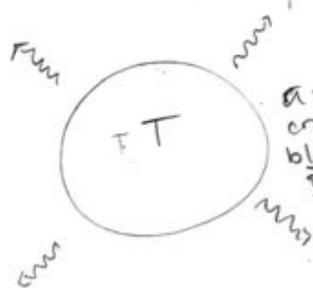

Photon - packet of light energy that behaves like a massless particle

$E = h\nu$

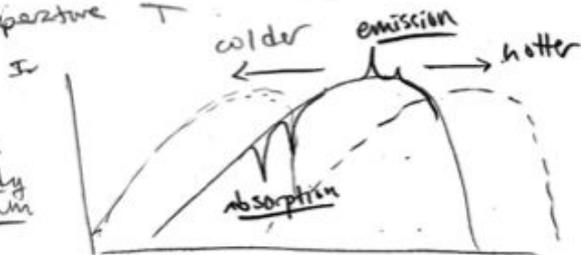

absorption
 $E = E_2 - E_1$
 $\lambda = \frac{hc}{E}$

Blackbody Radiation - radiation from an object with temperature T

a star creates a blackbody spectrum

lower frequency
 longer wavelengths
 (redder)

higher frequency
 shorter wavelengths
 (bluer)

\Rightarrow each chemical has unique absorption & emission lines

e.g. Hydrogen Balmer lines

- $n=3 \rightarrow 2$: 626.279 nm \rightarrow red
- $n=4 \rightarrow 2$: 486.176 nm \rightarrow cyan
- $n=5 \rightarrow 2$: 434.5412 nm \rightarrow blue

Blackbody Radiation

Radiation that is in thermal equilibrium (all photons at the same temperature)

Hotter = BLUE

Colder = RED

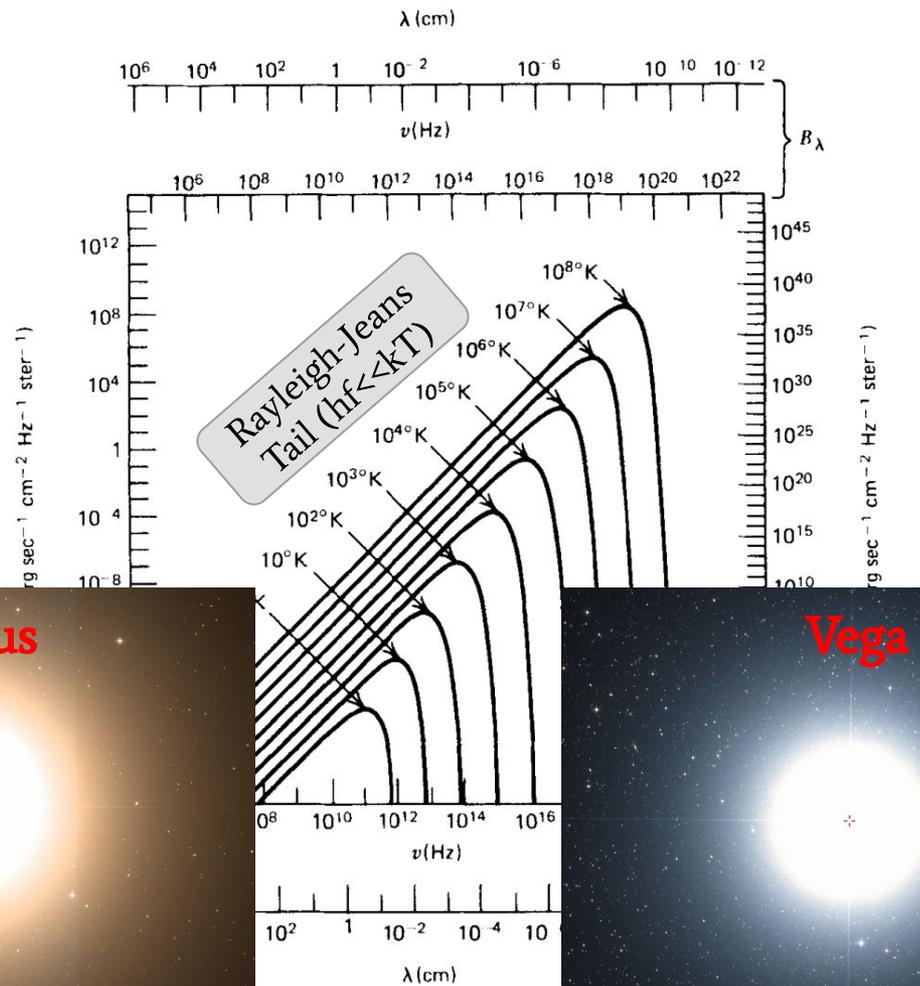

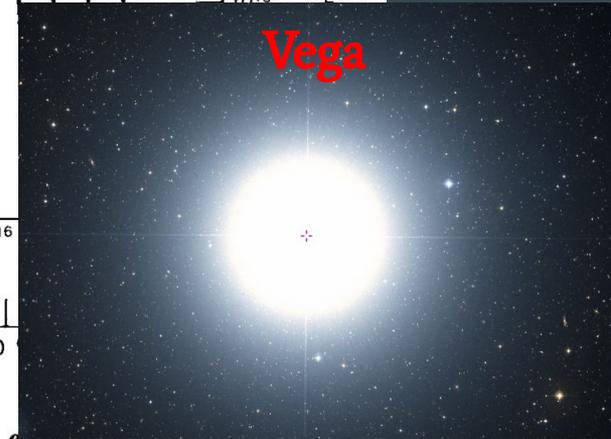

Figure 1.11 Spectrum of blackbody radiation at various temperatures (taken from Kraus, J. D. 1966, *Radio Astronomy*, McGraw-Hill Book Company)

Stellar Spectra

Stars' spectra tell us about their chemical content, environment, age, and speed!

Kirchoff's Laws:

1. perfect blackbody has continuous spectrum with no spectral lines
2. **hot diffuse gas** produces bright **emission** lines
3. **cool dense gas** in front of continuous spectrum source produces dark **absorption** lines

Spectra can be used to measure **radial velocities** of stars and **cosmological redshifts** (distances) of galaxies using the **doppler effect**:

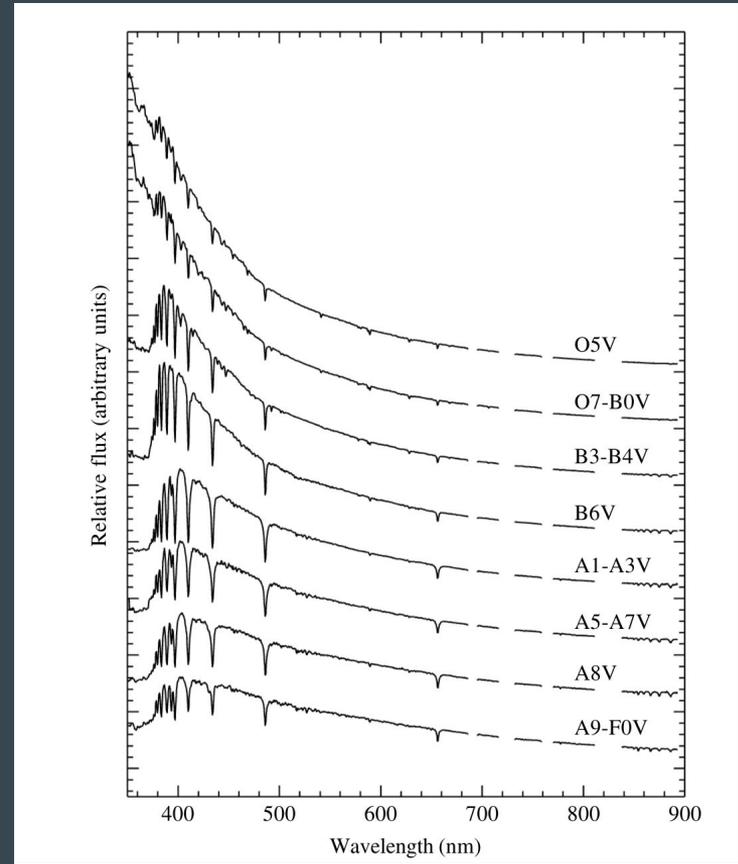

Radial velocity: $v = (\lambda c) \Delta \lambda$

Cosmological redshift: $z = \Delta \lambda / \lambda - 1$

Luminosity distance: $D = cz/H_0$ (Hubble's constant $H_0 \approx 70 \text{ km/s/Mpc}$)

Demo:

https://phys.libretexts.org/Courses/HACC_Central_Pennsylvania's_Community_College/Astronomy_103%3A_Introduction_to_Planetary_Astronomy/04%3A_Electromagnetic_Radiation/4.04%3A_Kirchhoffs_Laws

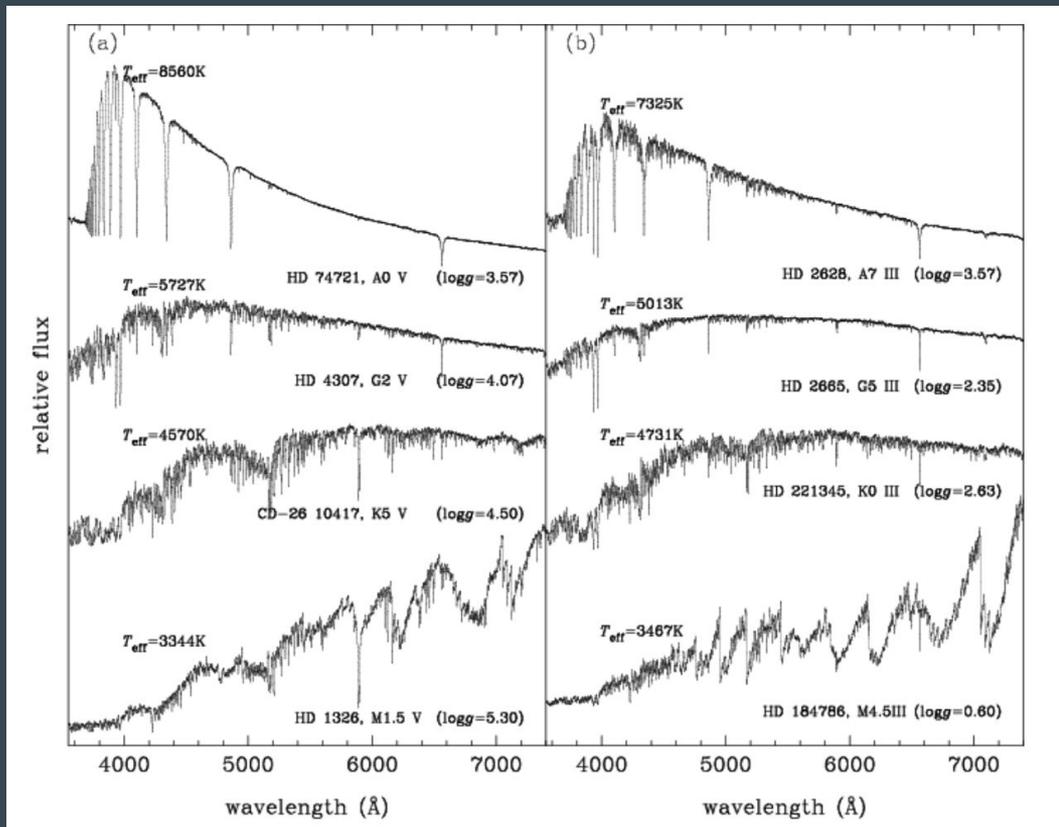

Sub-Giant Star Spectra
(Silva & Cornell 1992)

Think-Pair-Share

How would you distinguish which spectral lines come from the star and which ones come from gas in the Interstellar Medium?

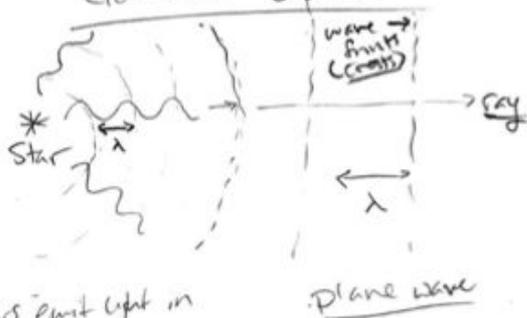

Stellar Spectra Examples

MILES Stellar Spectra
Library
(Falcón-Barroso+2011)
<https://research.iac.es/proyecto/miles/pages/stellar-libraries/miles-library.php>

Spectral Class	Color	Approximate Temperature (K)	Principal Features	Examples
O	Blue	> 30,000	Neutral and ionized helium lines, weak hydrogen lines	10 Lacertae
B	Blue-white	10,000–30,000	Neutral helium lines, strong hydrogen lines	Rigel, Spica
A	White	7500–10,000	Strongest hydrogen lines, weak ionized calcium lines, weak ionized metal (e.g., iron, magnesium) lines	Sirius, Vega
F	Yellow-white	6000–7500	Strong hydrogen lines, strong ionized calcium lines, weak sodium lines, many ionized metal lines	Canopus, Procyon
G	Yellow	5200–6000	Weaker hydrogen lines, strong ionized calcium lines, strong sodium lines, many lines of ionized and neutral metals	Sun, Capella
K	Orange	3700–5200	Very weak hydrogen lines, strong ionized calcium lines, strong sodium lines, many lines of neutral metals	Arcturus, Aldebaran
M	Red	2400–3700	Strong lines of neutral metals and molecular bands of titanium oxide dominate	Betelgeuse, Antares
L	Red	1300–2400	Metal hydride lines, alkali metal lines (e.g., sodium, potassium, rubidium)	Teide 1
T	Magenta	700–1300	Methane lines	Gliese 229B
Y	Infrared ¹	< 700	Ammonia lines	WISE 1828+2650

Geometric Optics

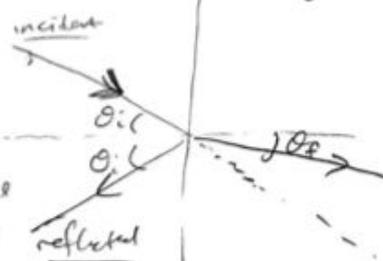

Stars emit light in all directions (isotropic)

air ($n=1$)

glass ($n > 1$)

Law of reflection: light is reflected at the angle of incidence

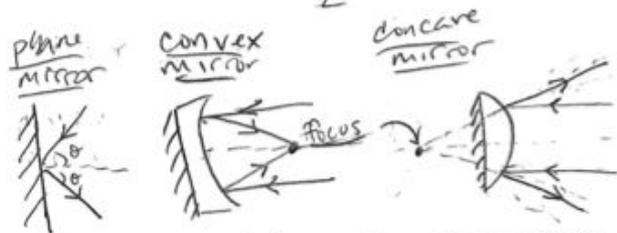

Snell's law of refraction

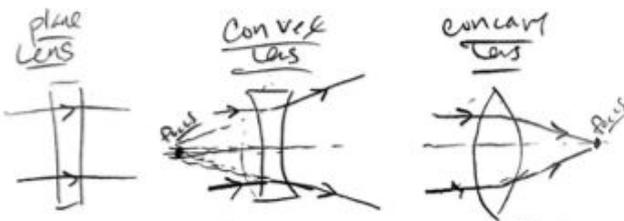

refracted transmitted light bends toward the normal in medium with $v < c$

index of refraction: $n = \frac{c}{v}$

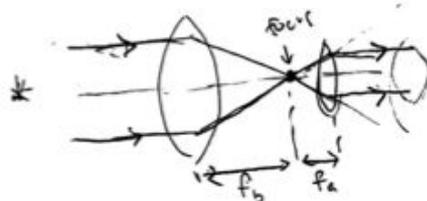

lens - uses refraction to

reflective telescope - uses mirrors to focus & magnify light

refractive telescope - uses lenses to focus & magnify light

magnification $M = \left(\frac{f_o}{f_e}\right)^2$

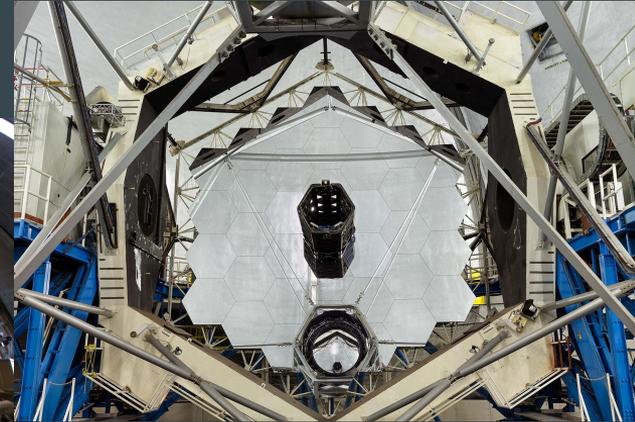

Telescope Design Examples

Palomar Hale Telescope - 200 inch Cassegrain telescope

Las Cumbres Observatories - 1 meter Ritchey-Chretien reflecting telescopes

Keck I & II telescopes - 10 meter Ritchey-Chretien reflecting telescopes with adaptive optics

Think-Pair-Share

Why are modern telescopes almost exclusively *reflective* telescopes?

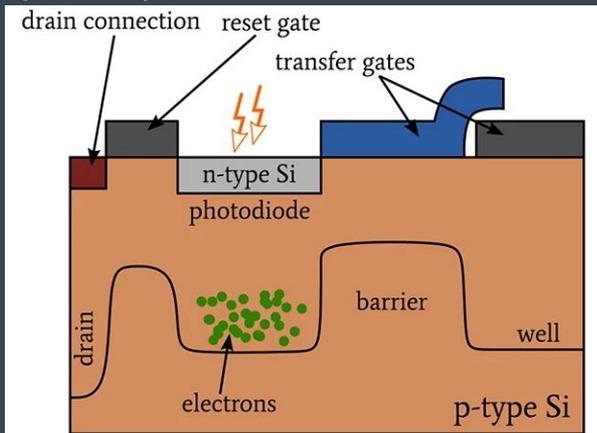

Demo: Let's go through the components of refractive binoculars and a reflective Gskyer telescope!

Detectors: Photographic Film/Plates

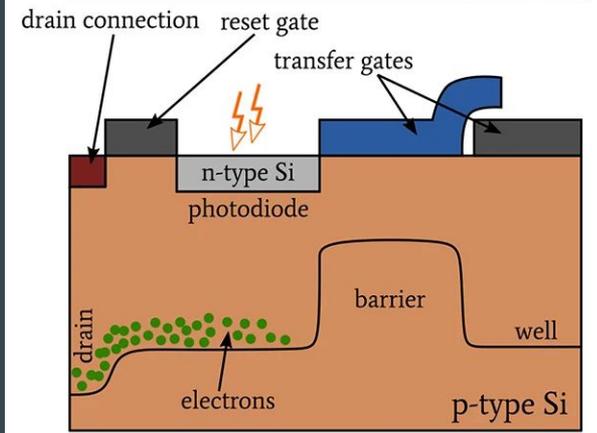

Detectors: Charge-Coupled Devices (CCD) & CMOS Detectors

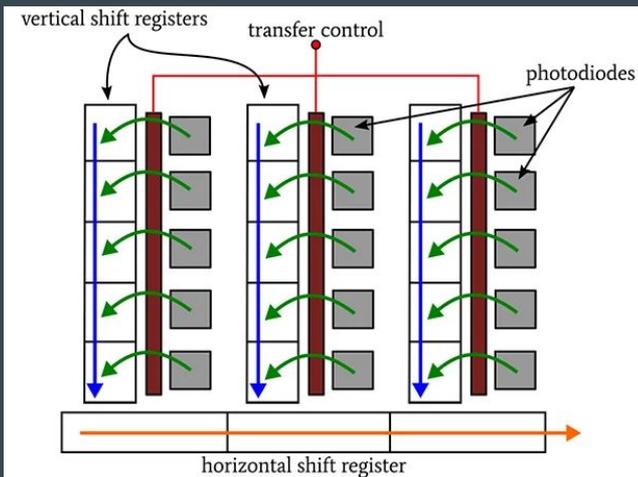

Detection

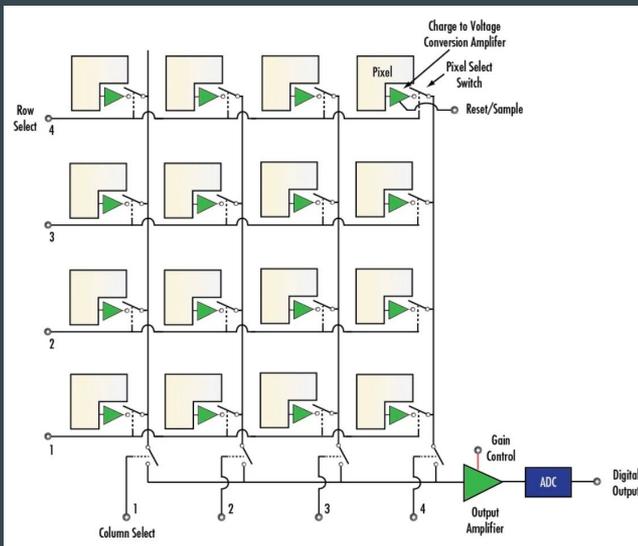

Readout

CCD

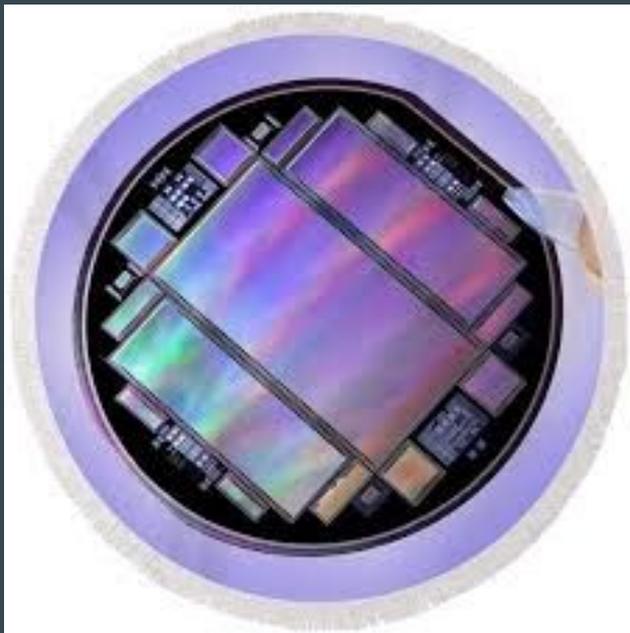

CMOS

Detectors: Charge-Coupled Devices (CCD) & CMOS Detectors

Keck Echelle Spectrograph
Imager (ESI) 2048 x 4096
CCD (15 μm pixels)

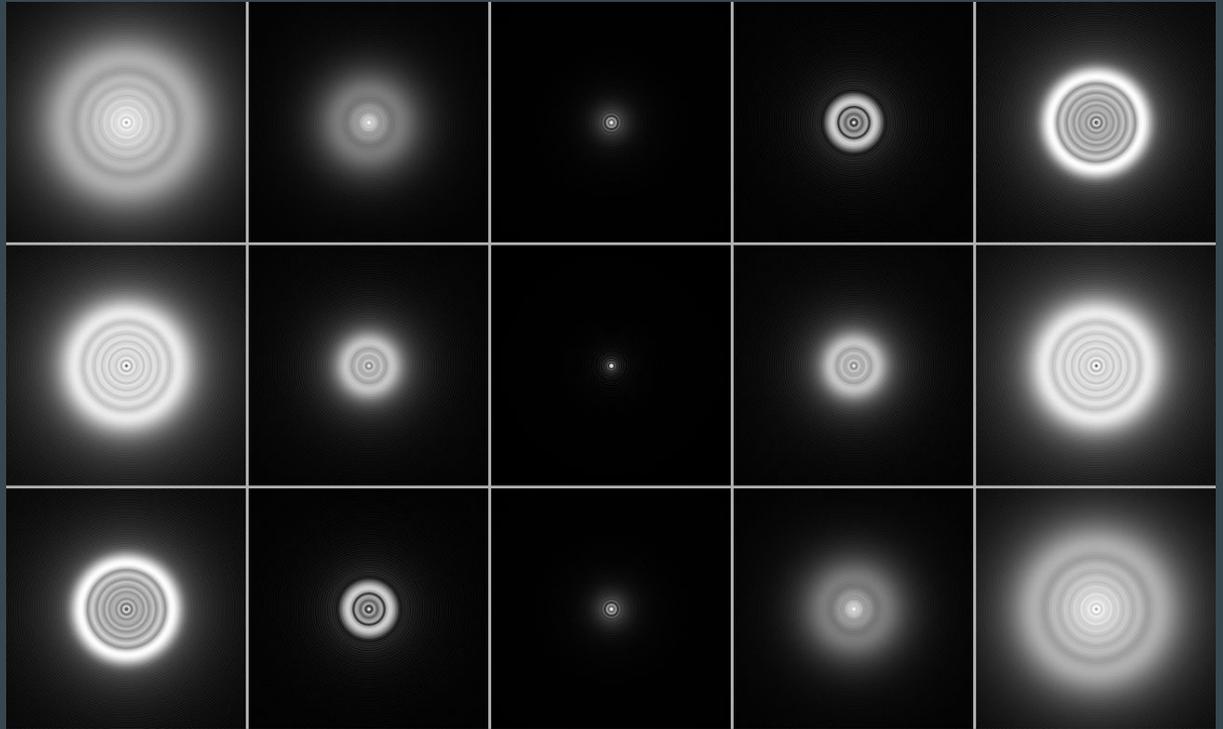

ESI CCD Characteristics	
Full-well depth	105,000e-
Read noise	2.7e-

4500 \AA	75.5%
5000 \AA	82.4%
6000 \AA	80.3%
6500 \AA	79.7%
7000 \AA	77.1%
8000 \AA	68.9%
9000 \AA	45.0%
10000 \AA	11.3%

Point Spread Function

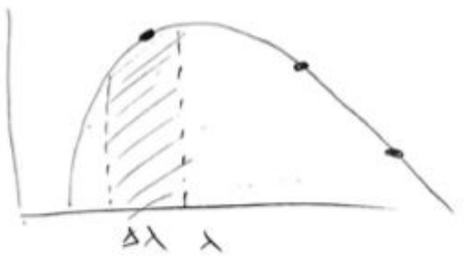

Spatial response of the detector due to the aperture size ; single lens makes an Airy function PSF (“spherical aberration”)

2.3/

Photometry - measuring brightness (flux) of a star in particular wavelength range using filters

- b Ultraviolet $100 \text{ nm} < \lambda < 400 \text{ nm}$
 - Optical $380 \text{ nm} < \lambda < 750 \text{ nm}$
 - Infrared $700 \text{ nm} < \lambda < 1 \text{ mm}$
- Photometric Systems
 extended ranges based on telescope filters
 e.g. UBVRI
 JHK

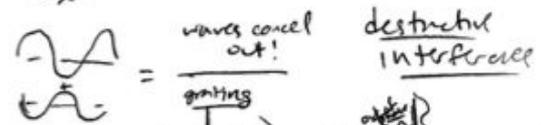

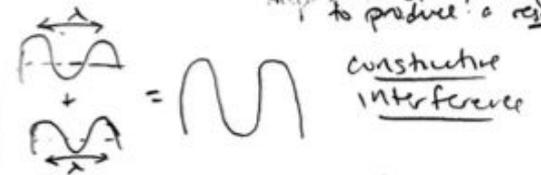

Magnitude - brightness in wavelength range (m_v)
color - difference in magnitude between different filters ($m_v - m_b$)

Spectroscopy - breaking light into its component wavelengths (dispersion) to measure high resolution spectrum

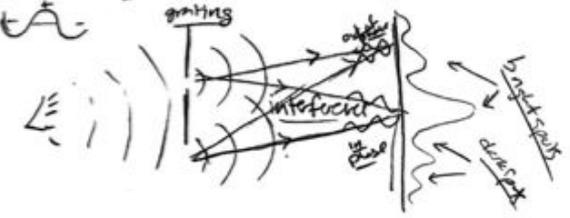

- Prism - uses wavelength dependence of index of refraction for dispersion

Superposition Principle - when 2 light waves add together, they interfere to produce a resultant

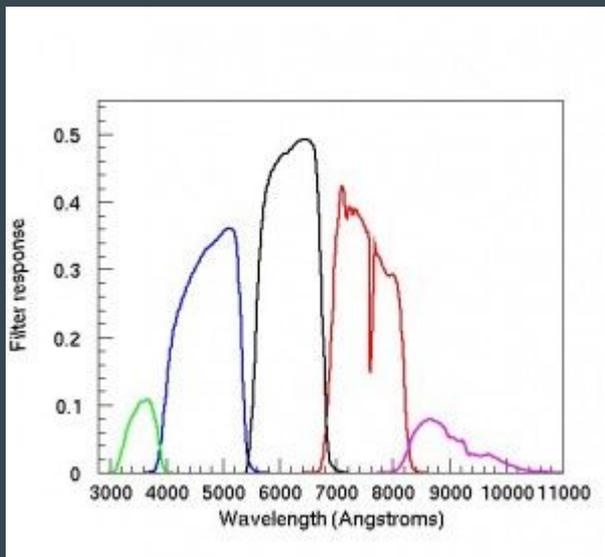

- Diffraction Grating - uses interference to disperse light

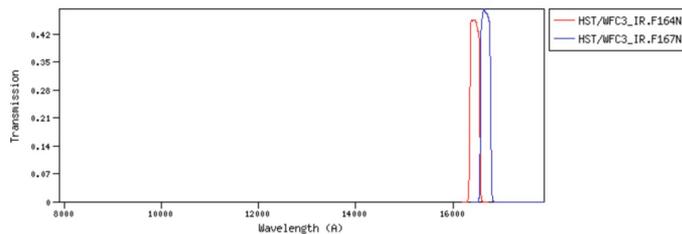

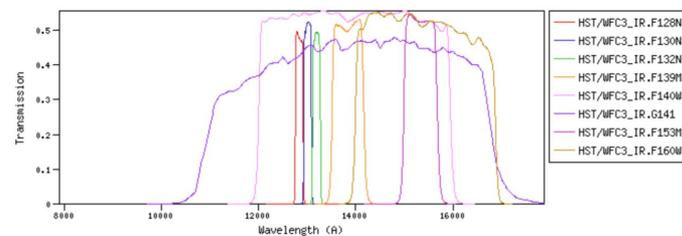

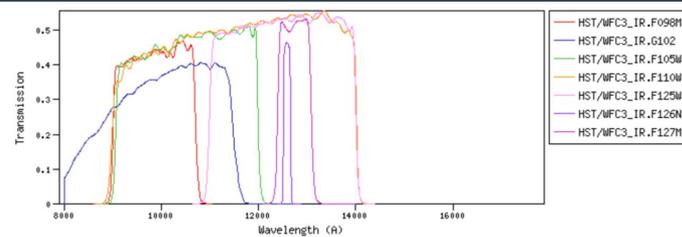

Photometric System Examples

SDSS

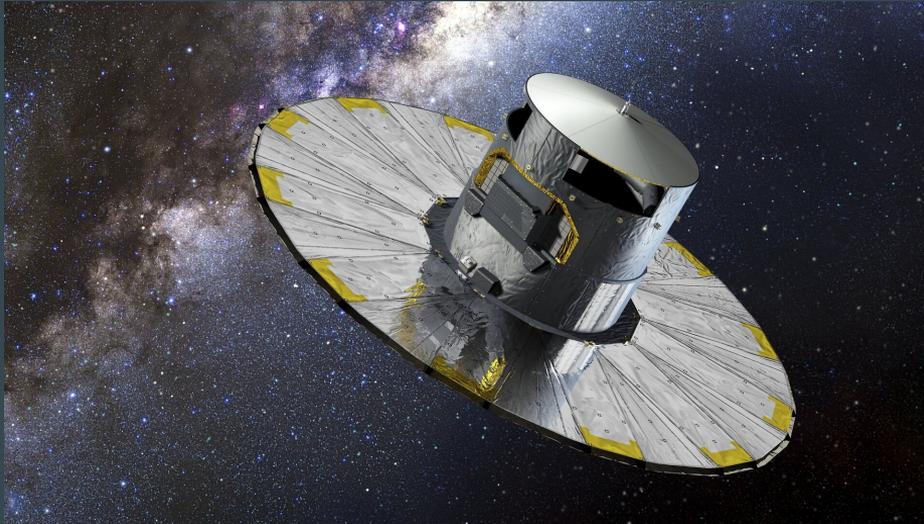

HST WideField IR Camera

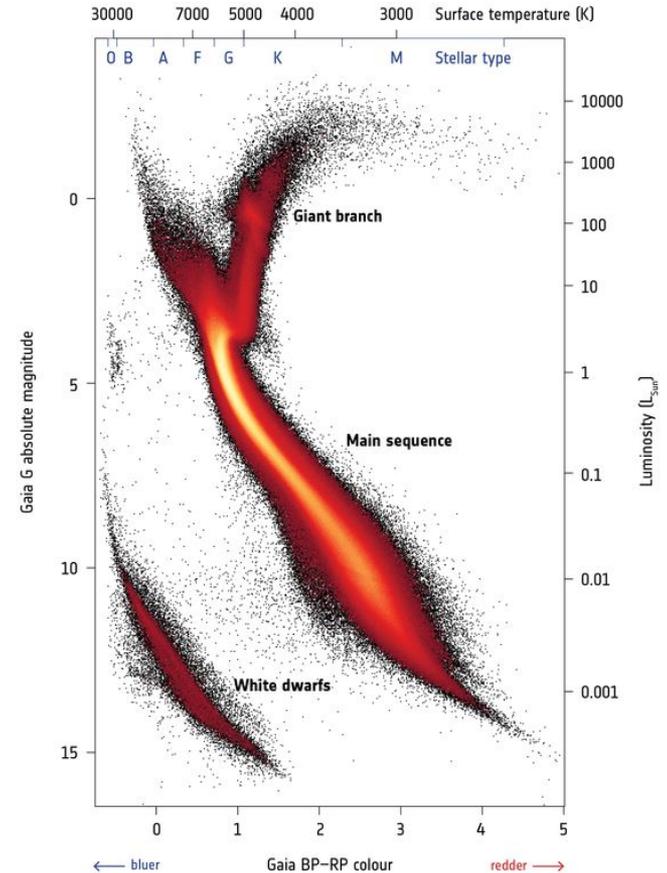

The Hertzsprung-Russell Diagram

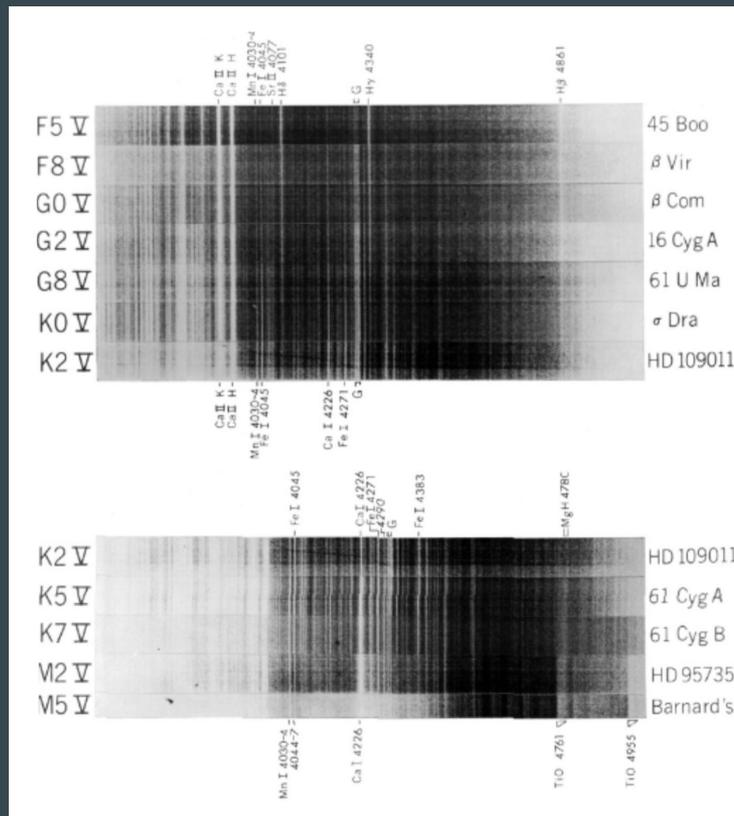

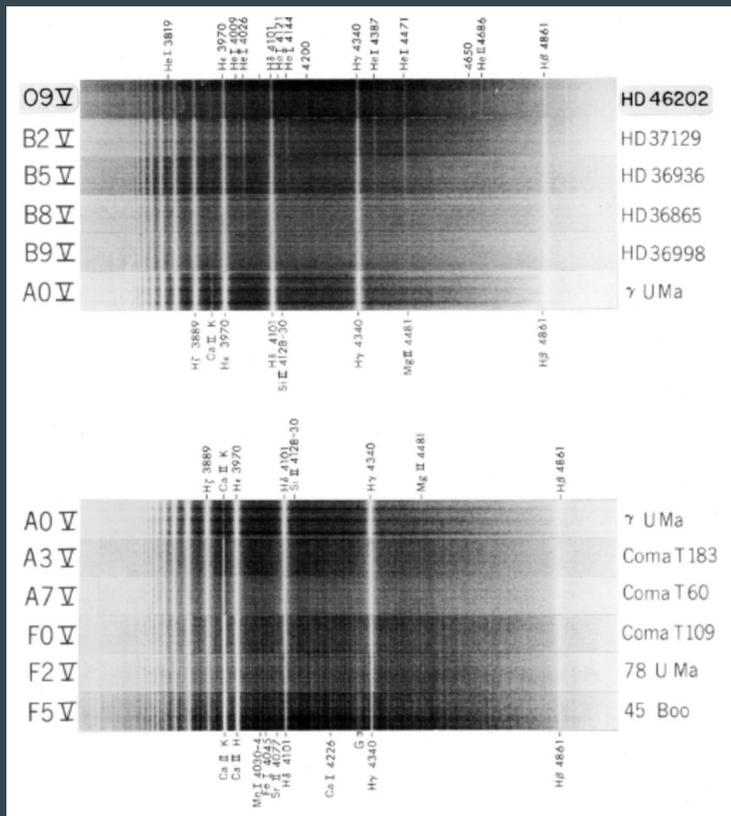

- **Color-Index** (B-V or BP-RP) closely relates to **stellar type (O-M)** and **effective surface temperature**
- European Space Agency's *Gaia* telescope has mapped over 2 billion stars to the H-R diagram!

→ GAIA'S HERTZSPRUNG-RUSSELL DIAGRAM

Stellar Spectra Examples - How do we measure stars' spectra?

$$d\sin\theta=2\lambda$$

Diffraction Gratings

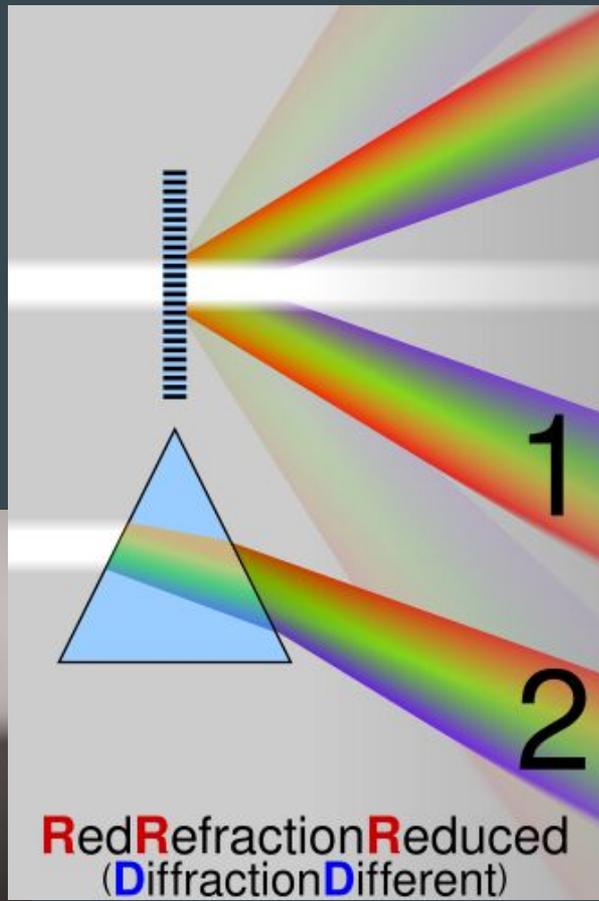

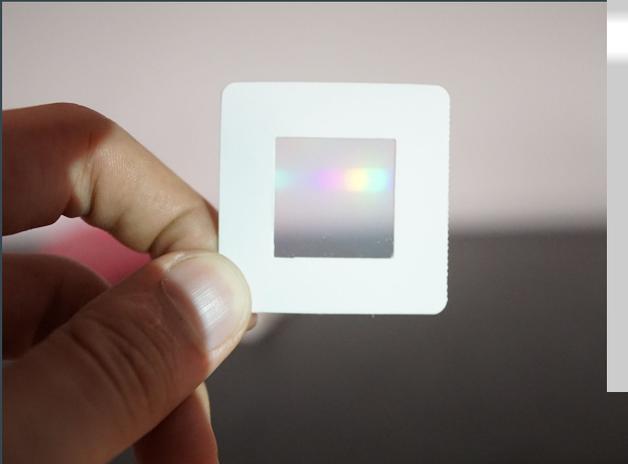

Series of N slits creates **interference** , or **diffraction** between light passing through

constructive interference : $d\sin\theta = m\lambda$

destructive interference: $d\sin\theta = (m+1/2)\lambda$

Resolution:

$$R = \Delta\lambda/\lambda = Nm$$

$$d\sin\theta=\lambda$$

$$d\sin\theta=0$$

$$d\sin\theta=-\lambda$$

Lecture 3: Radio Astronomy and Compact Stellar Remnants

...

Learning Objectives and Overview

By the end of this course, students will be able to:

...identify major stars and constellations in the night sky, recount the life-cycle of a star from the Main Sequence to supernova, and distinguish between White Dwarfs, Neutron Stars, and Black Holes.

...describe the basic components of an optical telescope, explain the major differences between optical, infrared, and UV astronomy, describe why X-ray and gamma ray telescopes operate differently from OIR and UV telescopes.

...describe the basic components of a radio antenna, explain how radio interferometers work, and list the astrophysical sources of radio waves.

...describe the components of a galaxy (disk, bulge, ISM, halo, CGM), define cosmology, how it is studied (redshift, CMB, 21 cm cosmology, simulations, FRBs), explain how distance, redshift, and time are related within general relativity, and understand how the presence of dark matter and dark energy affect our picture of the Universe.

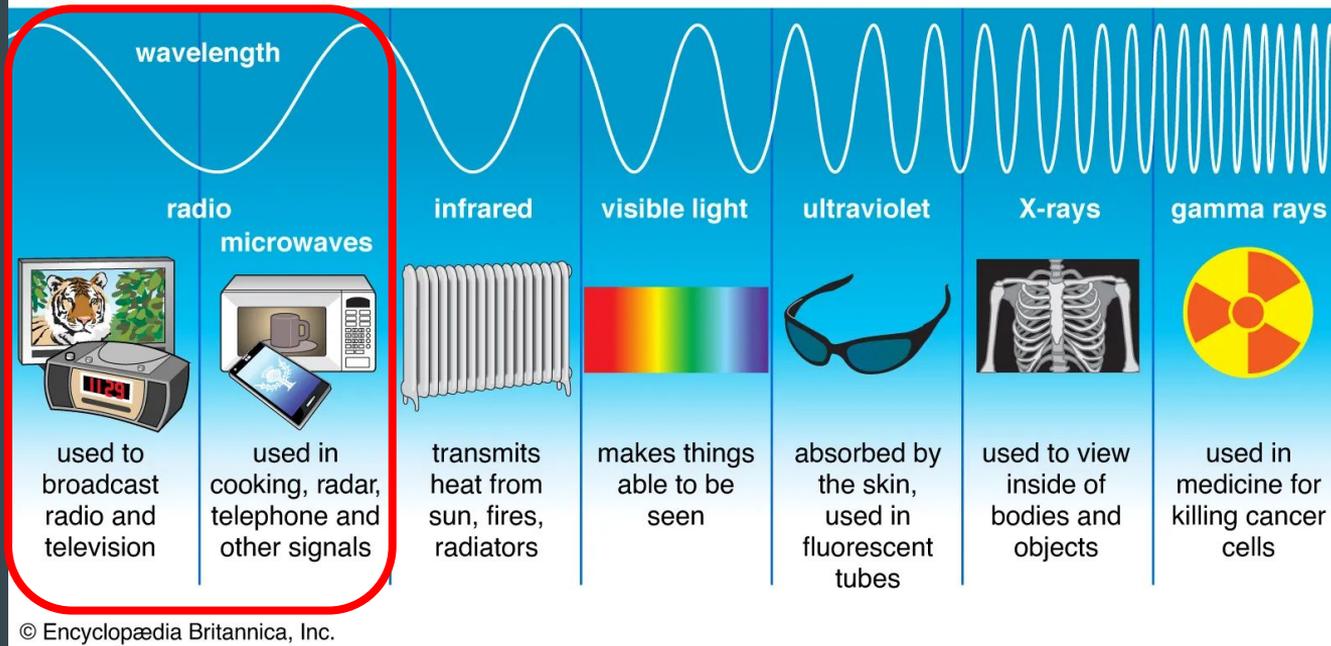

...list some of the major questions in astronomy today and refer to resources to continue exploring astronomy within and around Pasadena.

Recap: What is Light?

Light is **energy** that travels in **waves** carried by **electric and magnetic fields**

All waves have a wavelength and speed $c=671$ million miles per hour = 299 million meters per second

Types of Electromagnetic Radiation

Light can also be defined as particles, **photons**, which are discrete **quanta** of electromagnetic fields

Recall: Atmospheric Windows

Radio light has
wavelengths from
1 mm - 10 m

frequencies
from 10 kHz
- 3 THz

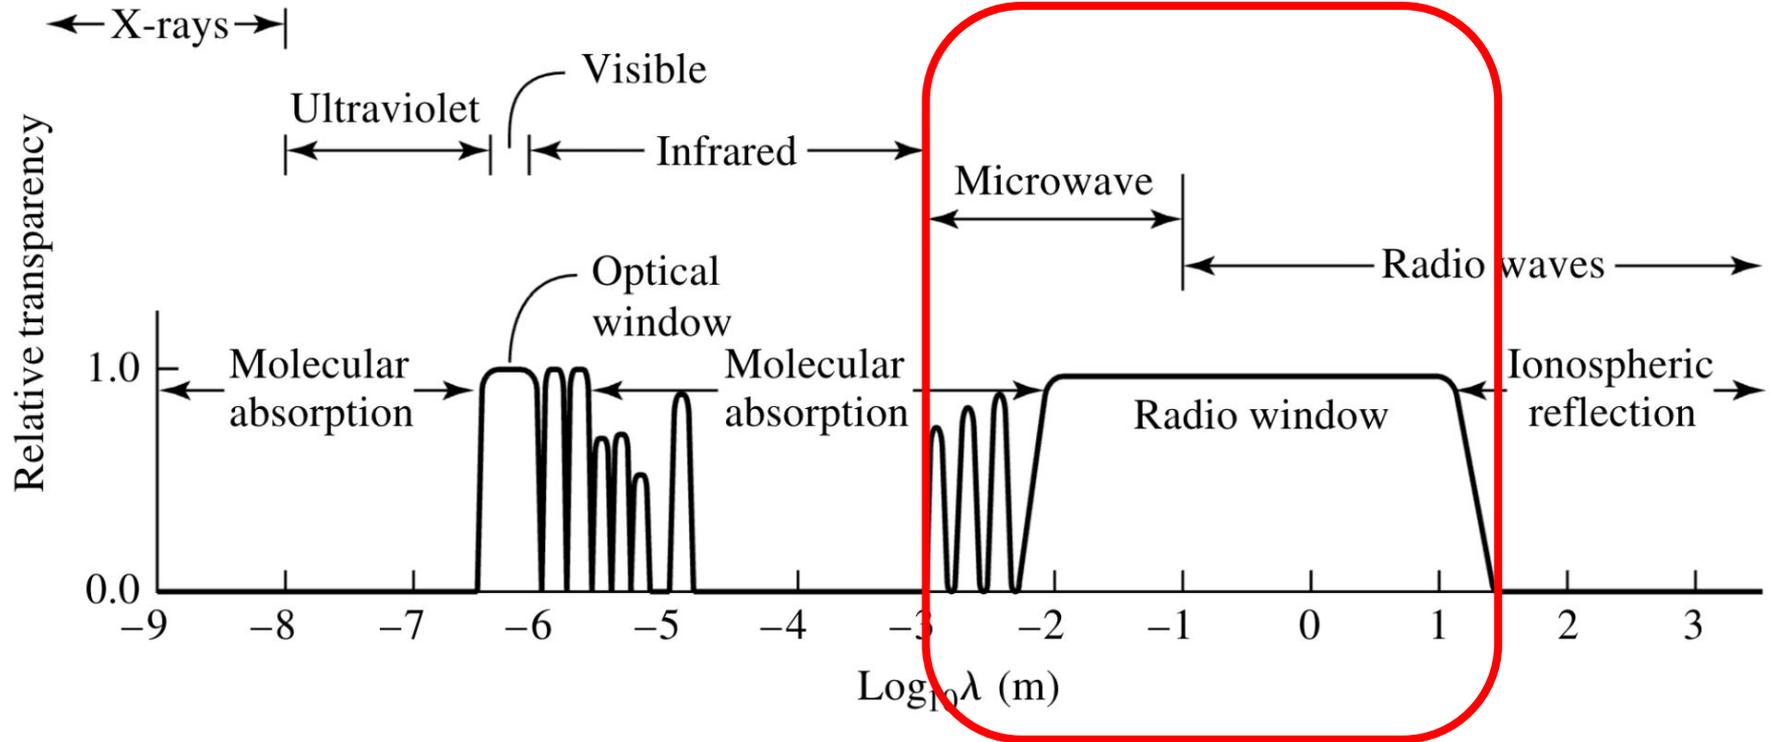

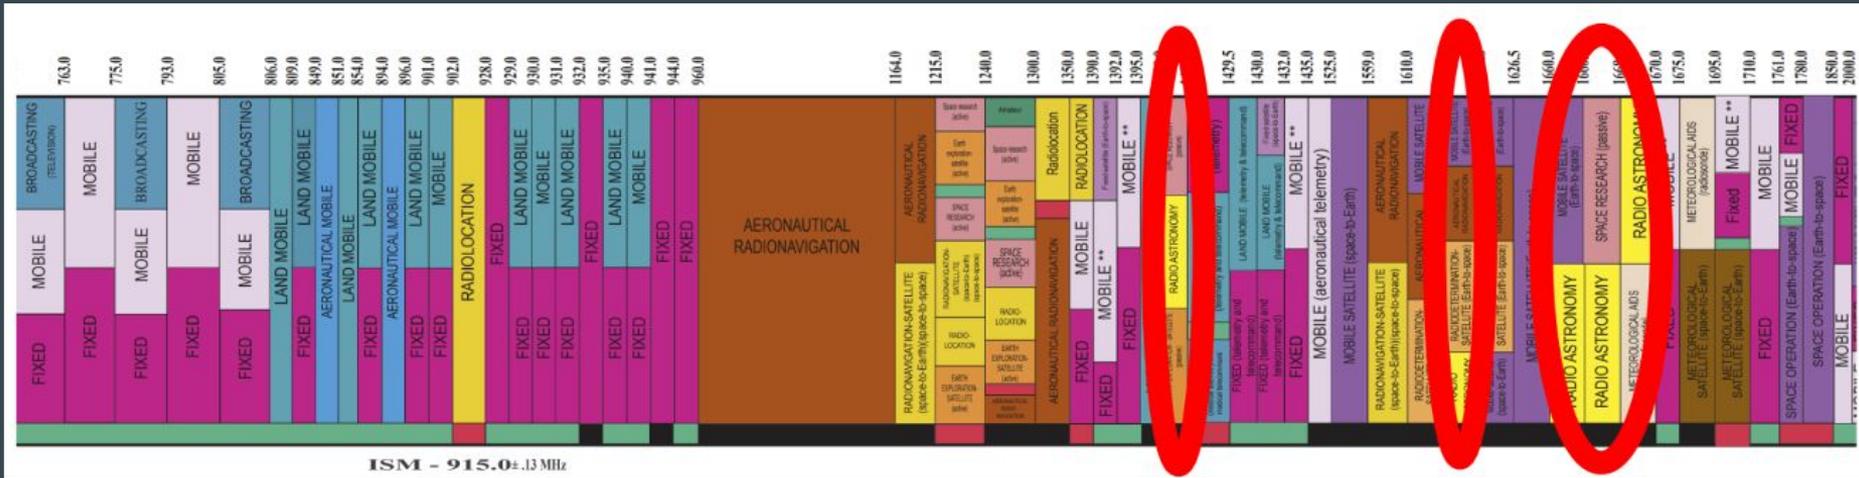

FIGURE 6.25 The transparency of Earth's atmosphere as a function of wavelength.

Radio Spectrum Allocations

The Federal Communications Commission (FCC) and International Telecommunications Union (ITU) regulate the frequency spectrum and reserve specific “bands” (frequency/wavelength ranges) for communications, television, GPS, satellites, HAM radio, radio astronomy, and more.

For example, FM radio uses 88-108 MHz while radio astronomy often uses 400-800 MHz various sub-bands between 1-2 GHz

IEEE Standard Radio Bands

Band Designation	Nominal Frequency Range
HF	3-30 MHz
VHF	30-300 MHz
UHF	300-1000 MHz (Note 5)
L	1-2 GHz
S	2-4 GHz
C	4-8 GHz
X	8-12 GHz
Ku	12-18 GHz
K	18-27 GHz
Ka	27-40 GHz
V	40-75 GHz
W	75-110 GHz
mm (Note 9)	110-300 GHz
Sub-mm	>300 GHz

Recall: Blackbody Radiation

Radiation that is in thermal equilibrium (all photons at the same temperature)

Rayleigh-Jeans Law:

$$I_{\nu} = 2\nu^2 kT / c^2$$

Brightness Temperature:

$$T_b = c^2 I_{\nu} / 2k\nu^2$$

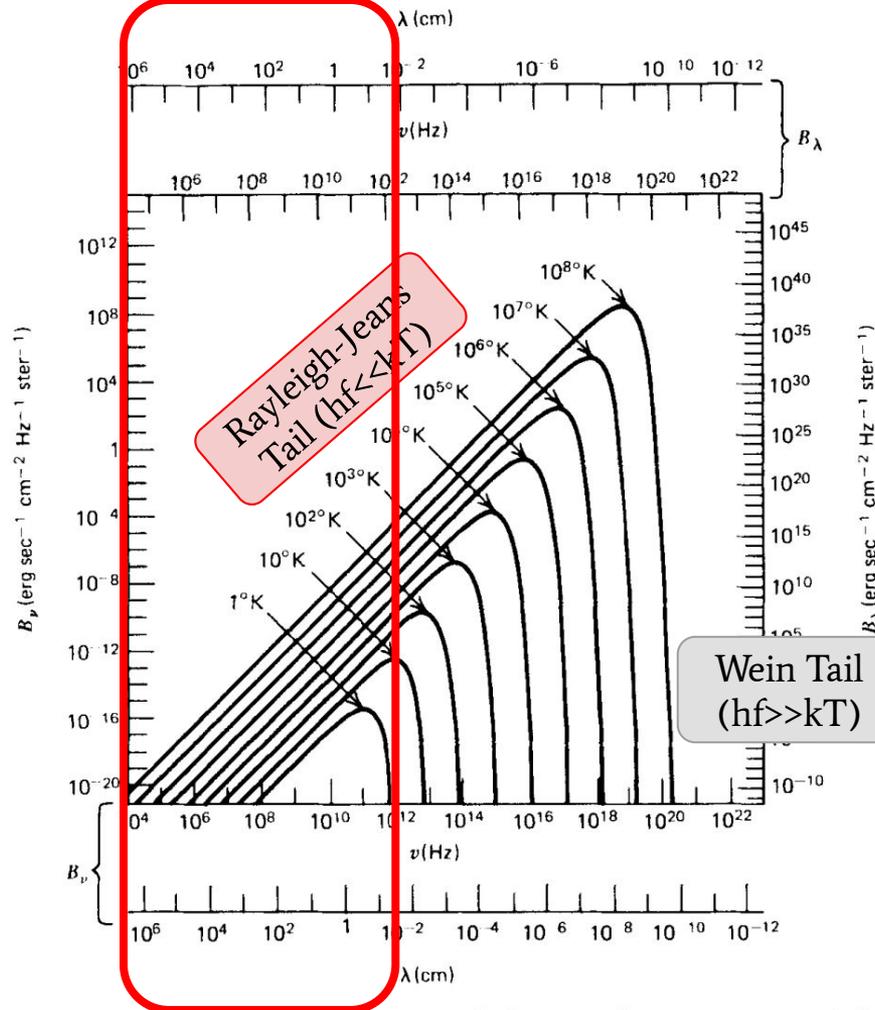

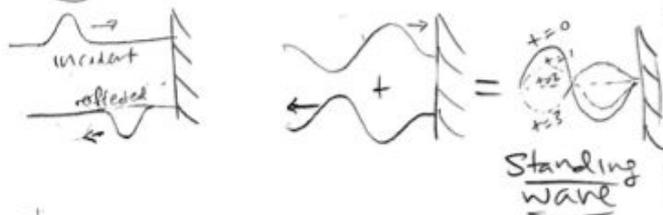

Figure 1.11 Spectrum of blackbody radiation at various temperatures (taken from Kraus, J. D. 1966, Radio Astronomy, McGraw-Hill Book Company)

3.3

Antenna - converts radiation in space into electrical current or vice versa

superposition / interference

Standing wave modes - only certain wavelengths are allowed to create standing waves!

$$\lambda_n = \frac{2L}{n}$$

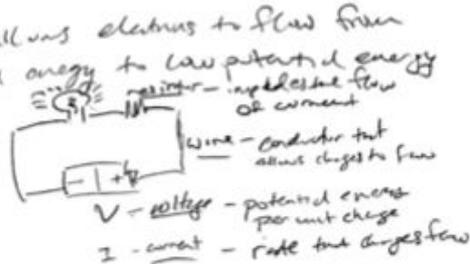

← length of string
← any number

incident and reflected wave interfere to produce a wave that appears stationary

Circuit - allows electrons to flow from high potential energy to low potential energy

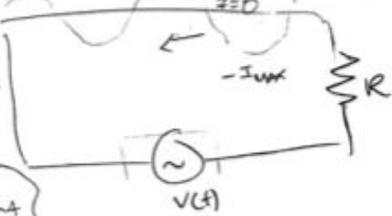

Ohm's law

$$V = IR$$

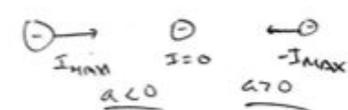

alternating current - current oscillates with time

↳ current on wire behaves like waves on a string!
↳ charges accelerate

wire with alternating current radiates (transmission)

EM waves that hit a wire induce a current (receiving)

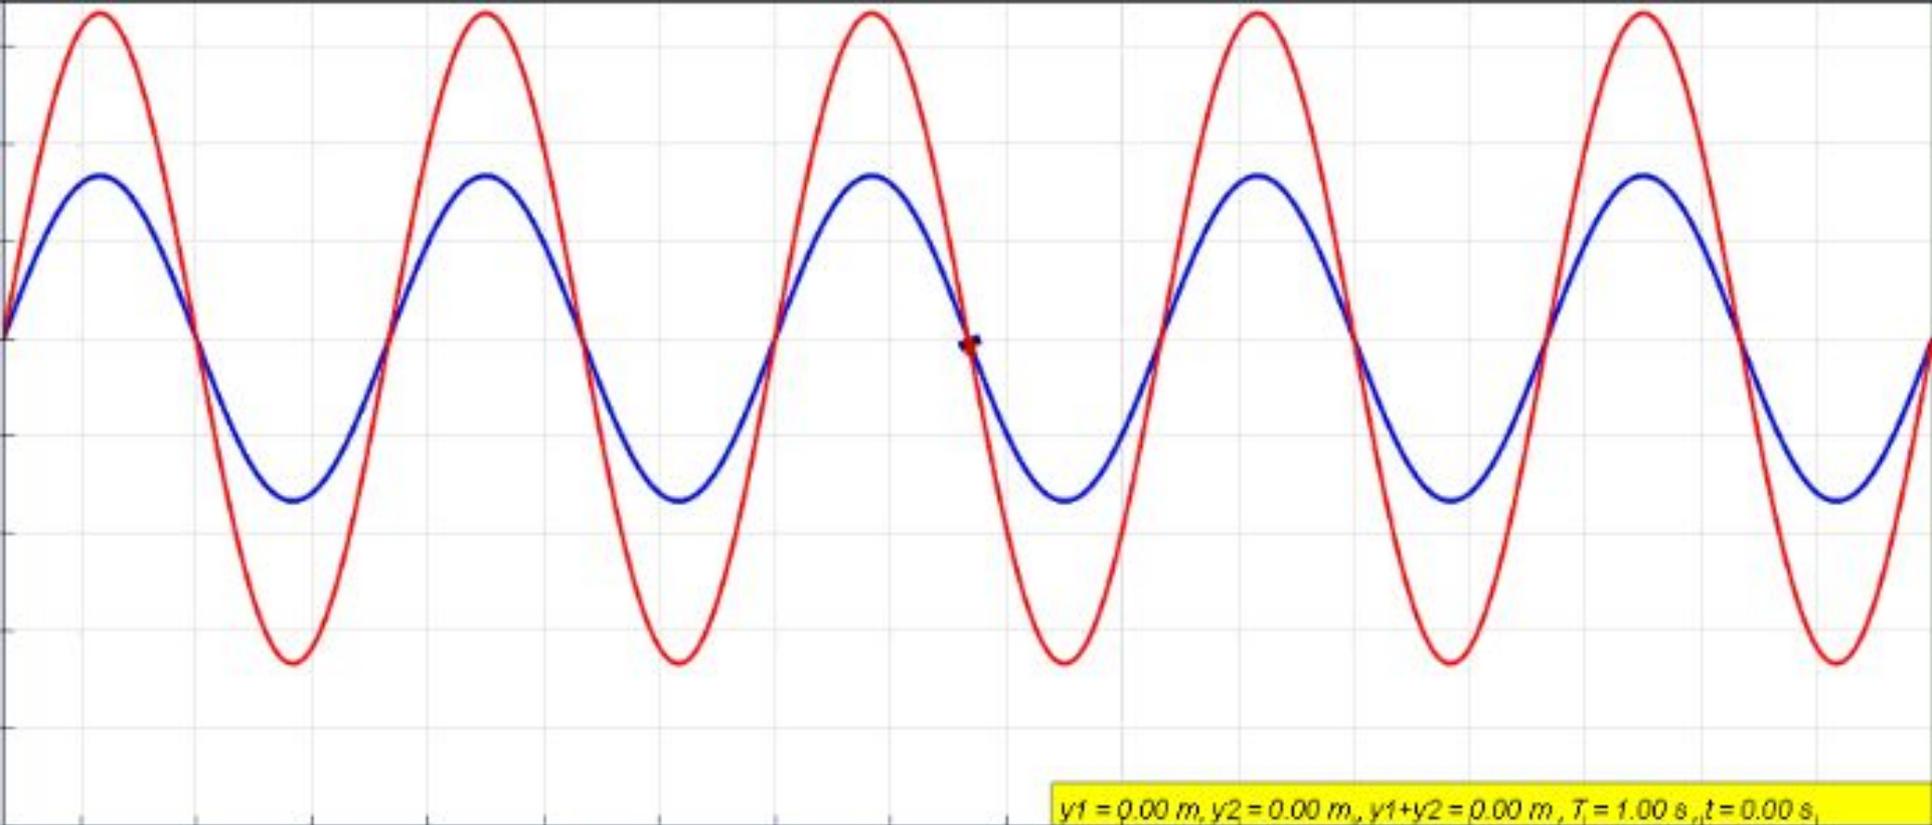

- Terminated wire ⇒ standing wave
I=0

$$\lambda_n = \frac{2L}{n}$$

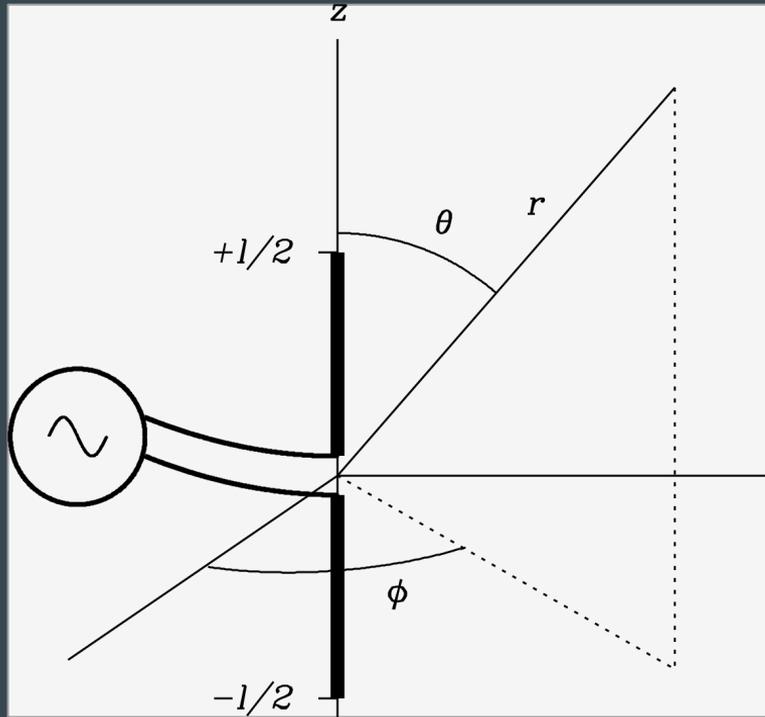

half-wave dipole: $L = \frac{\lambda}{2}$

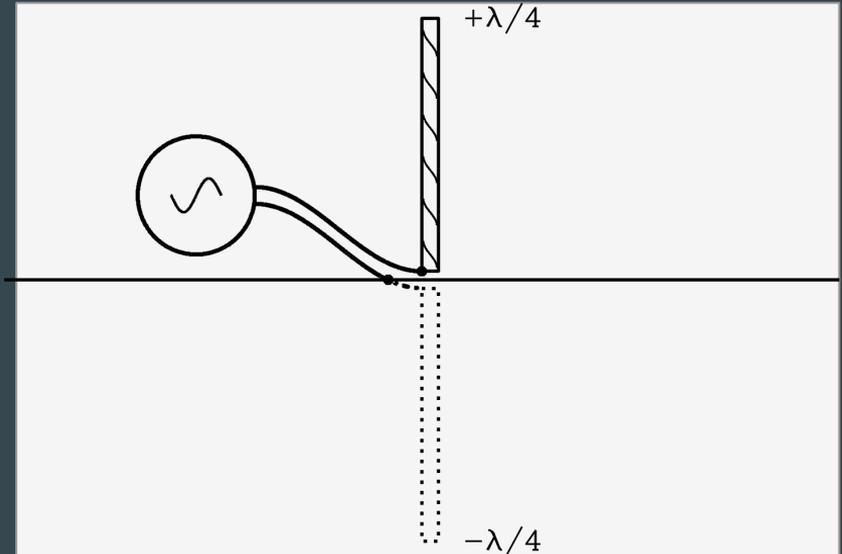

Standing Waves

Half-Wave Dipole Antenna

Ground-Plane Dipole Antenna

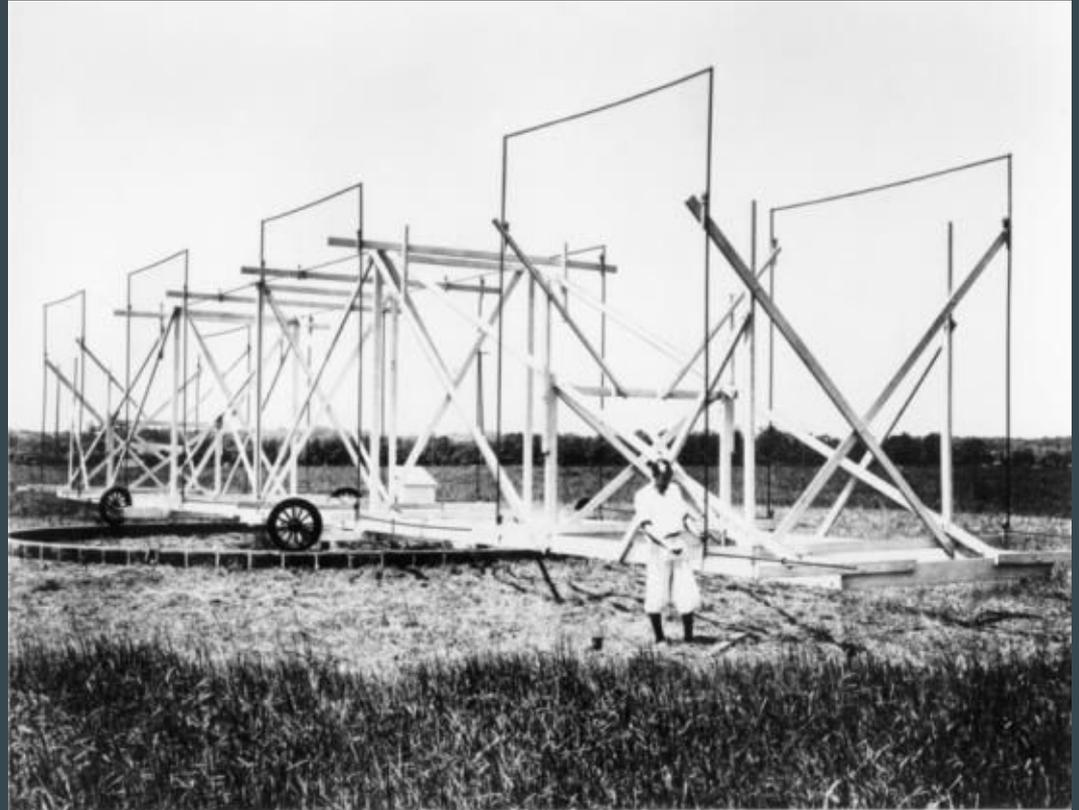

Karl Jansky's Radio Telescope (1932)

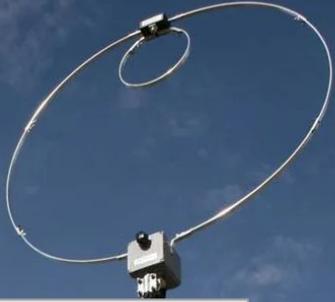

Bell Telephone Laboratories

Karl Jansky discovered “Electrical disturbances of apparently extraterrestrial origin” at 20 MHz – first evidence of astrophysical radio waves!

Unit of flux density: **Jansky (Jy)**

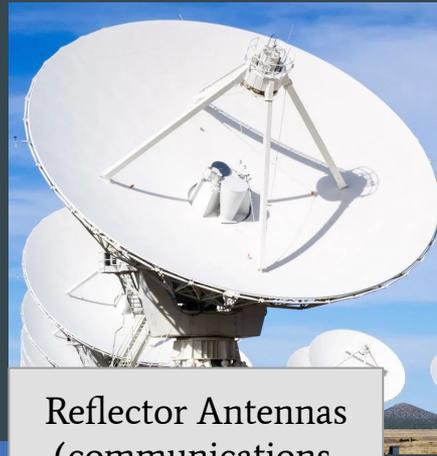

The Antenna Family

Loop Antennas
(direction finders,
radio receivers)

Horn Antennas
(radar)

Reflector Antennas
(communications,
astronomy)

Wide Band Antennas
(adjustable
wavelength range)

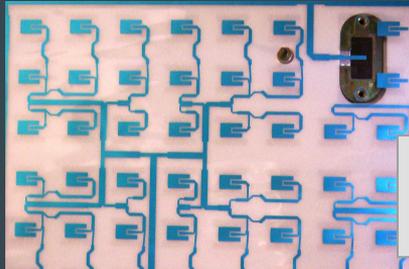

Yagi Antennas
(VLF, LF)

Helical antennas
(weather, GPS,
astronomy)

Lens antennas
(mm-wavelengths)

Patch, Microstrip Antennas
(cell phones)

3.4

Dish - reflects & focuses radio waves towards the antenna

↳ Bigger dish = higher sensitivity
= higher resolution

↳ Antenna capacitance - capacitive of resistor dissipating some power output by antenna

Redman's Equation: $\sigma_T \approx \frac{T_{\text{ant}} + T_{\text{rx}} + T_{\text{sys}}}{\sqrt{2 \times BW \times t_s}}$

↑ noise temperature ↑ range of frequency ↑ sampling time

→ minimum signal we can detect

(antenna pattern)

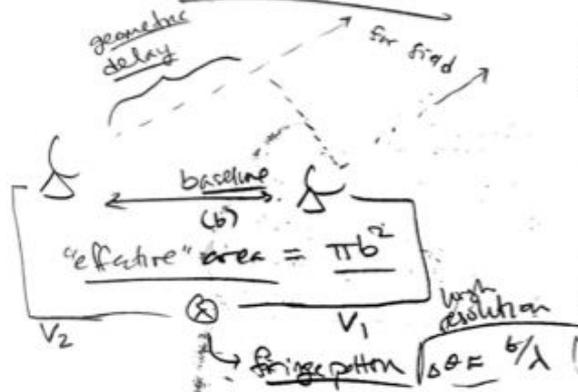

Interferometer - 2 or more radio antennas combined to increase the area

↳ cross correlation - multiply and average signals from 2 antennas

↳ interferometer sensitivity for N antennas:

$$\sigma_T = \frac{T_{\text{ant}} + T_{\text{rx}} + T_{\text{sys}}}{\sqrt{N(N-1) \Delta V t_s}}$$

large N = low σ_T = high sensitivity

Single-Dish Telescopes

305 Meter Arecibo Telescope
(Arecibo, Puerto Rico)

Five-Hundred-Meter Aperture
Spherical Telescope (FAST;
Guizhou, China)

Parkes Murriyang 64 Meter
Telescope (Parkes Australia)

Green Bank 100 Meter Telescope
(Green Bank, West Virginia)

Demo: Let's experiment with our own miniature interferometer!

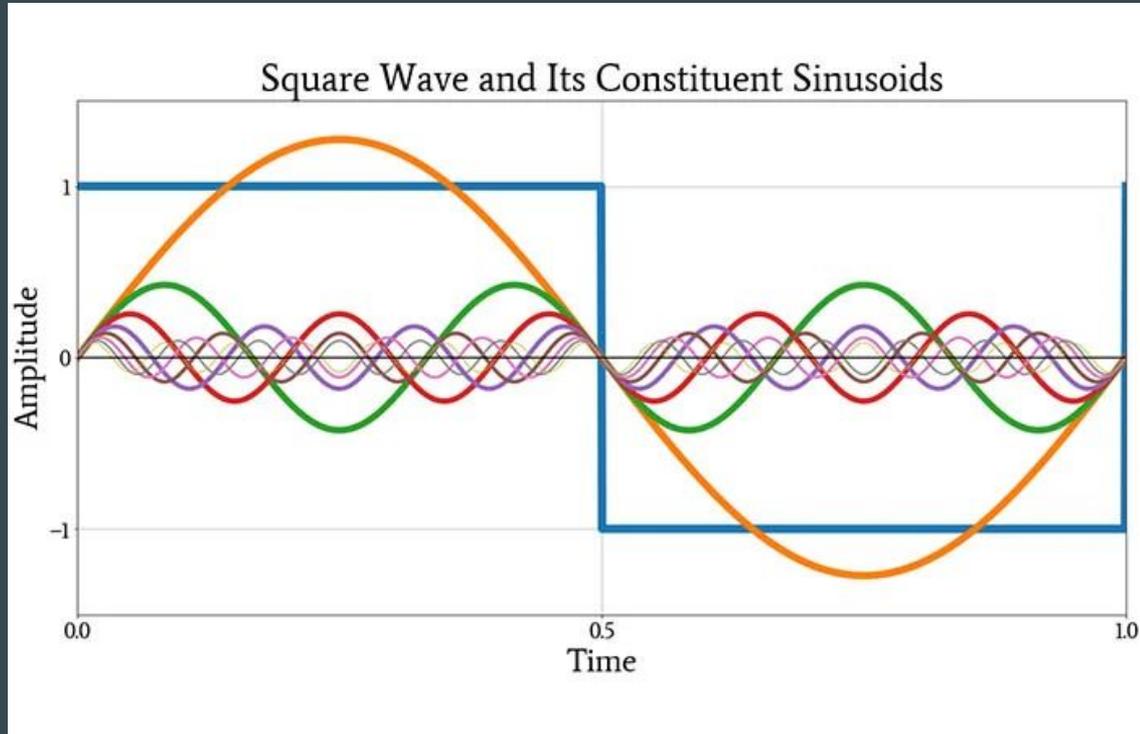

What happens when we add/remove components of the interferometer?

What allows us to build such a small optical interferometer, while radio interferometers can span hundreds of miles?

Fourier Representation of Signals

Any real signal can be represented by a sum of sinusoids with **fourier amplitudes** →

Any **complex** signal can be represented by a sum of complex exponentials with **fourier amplitudes**

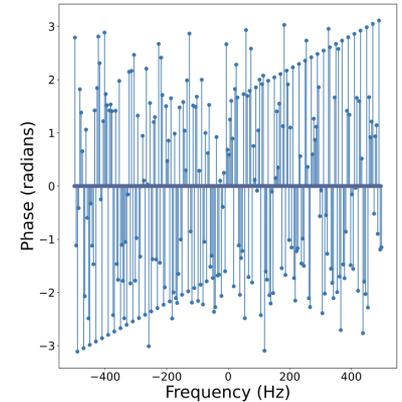

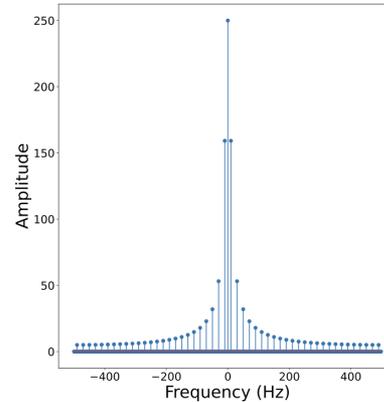

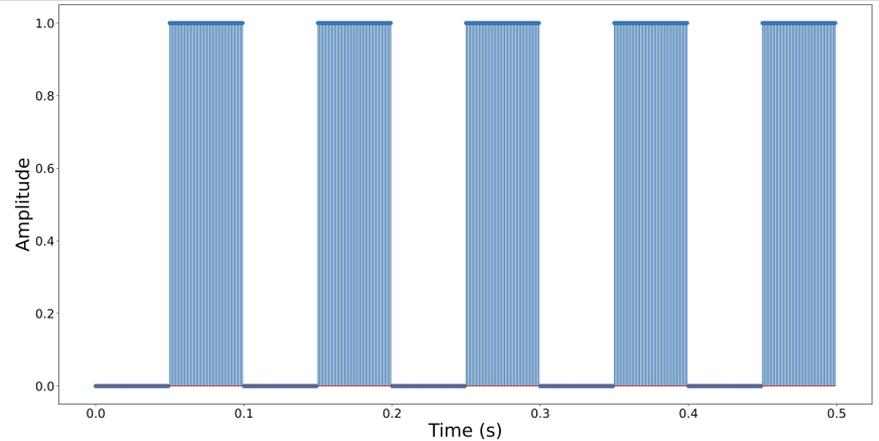

Fourier Representation of Signals

Discrete Fourier Transform
converts time domain signal to
fourier domain (frequency)
representation:

$$\text{DFT: } F[k] = \sum f[x] e^{-2\pi i k x / N}$$

$$\text{iDFT: } f[x] = (1/N) \sum F[k] e^{2\pi i k x / N}$$

Fast Fourier transform is an
algorithm to compute the
DTFT quickly and efficiently

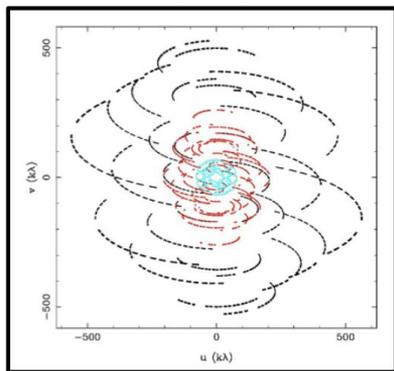

Radio Imaging

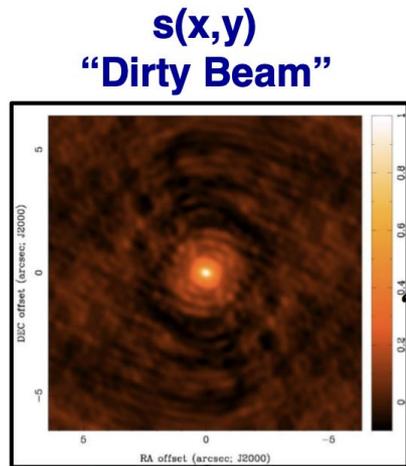

Stages of Imaging:

1. Grid to UV plane
2. FFT
3. “Clean”
(convolve with PSF)

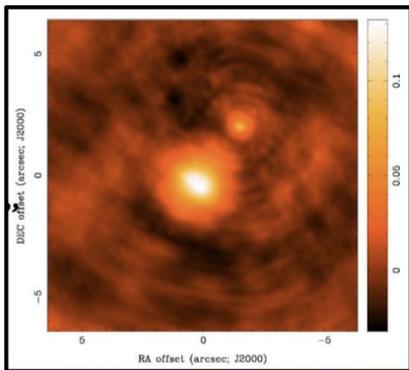

The Dirty Beam

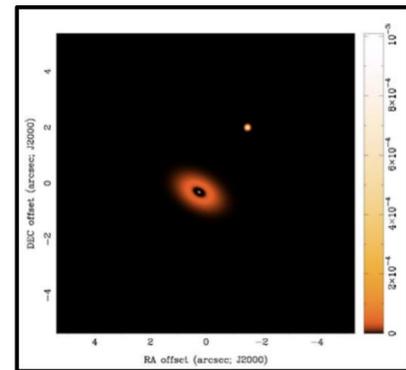

FT →

*(Convolution)

←

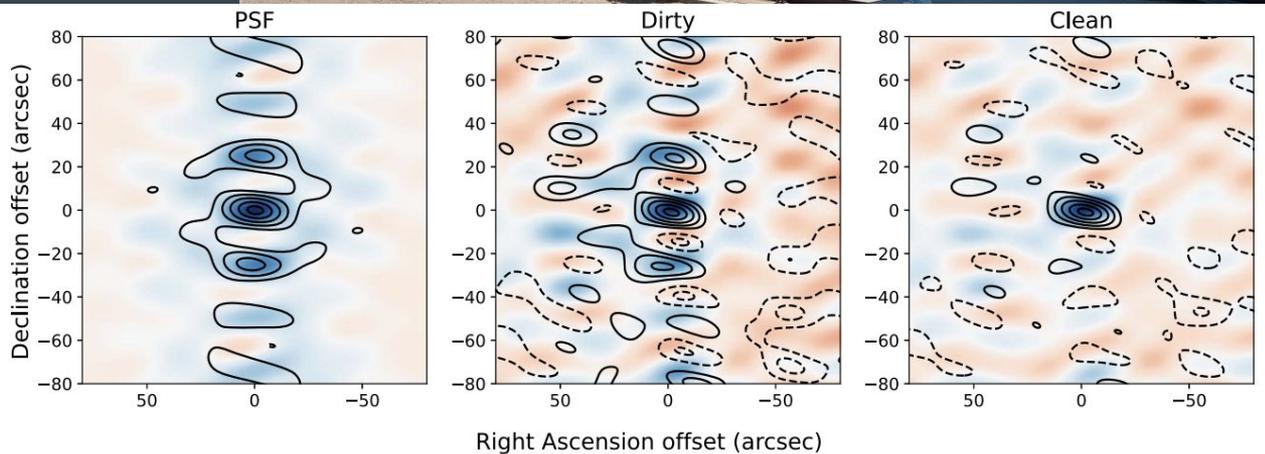

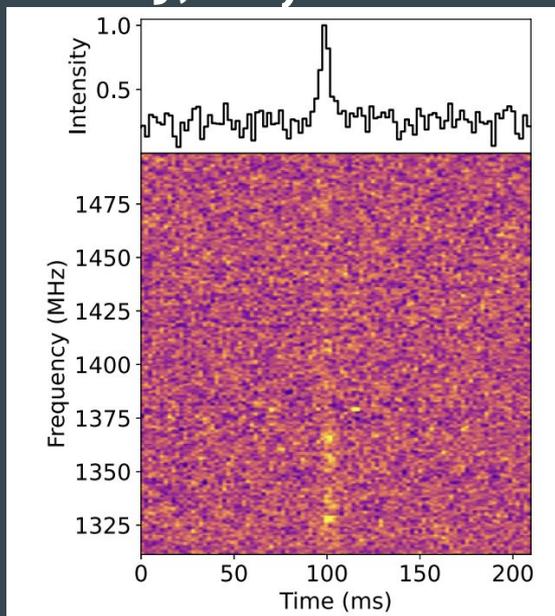

$T_D(x,y)$
“Dirty Image”

$T(x,y)$

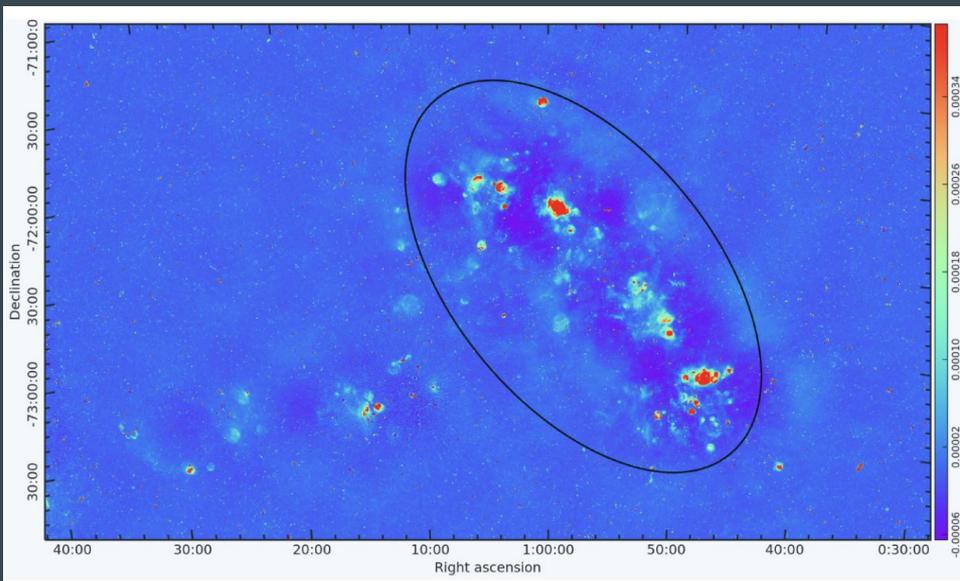

Examples: DSA-110 (97x10 meter antennas, Owens Valley, CA)

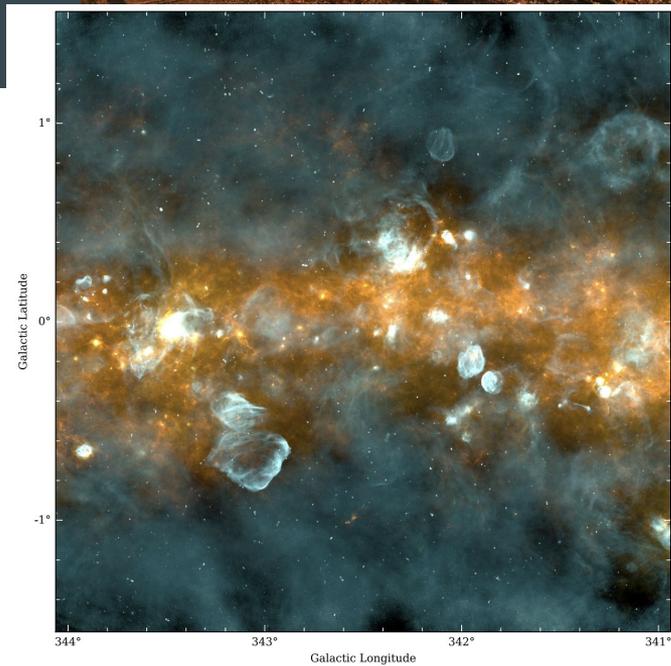

Fast Radio Burst (FRB) detected and localized by the DSA-110 (Ravi et al., 2023)

Examples: MeerKAT (64x13.5 meter antennas, South Africa)

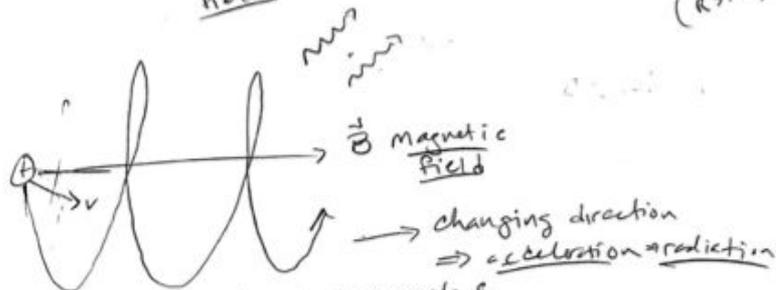

Radio Image of the Small Magellanic Cloud (Cotton et al., 2024)

IR + Radio Image of Galactic Plane (Goedhart et al., 2024)

3.7 |

Radiation - electromagnetic waves from a accelerating charged particle detectable in the far field

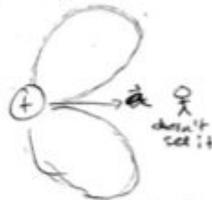

a charged particle in a magnetic field moves in a helix

Cyclotron radiation

charged particle in \vec{B} field moves non-relativistically ($v \ll c$)

$$v_c = \frac{qB}{2\pi m}$$

$$P = \frac{2}{3} \frac{q^2 a^2}{c^3}$$

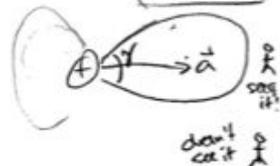

Synchrotron radiation

charged particle in \vec{B} field moves relativistically ($v \approx c$)

$$v_s = \frac{qB}{2\pi \gamma m}$$

$$\gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}}$$

relativistic factor

Incoherent radiation - N particles radiate separately relativistic boost

$$P_{total} = N \times P$$

coherent radiation - N particles radiate together

$$P_{total} = N^2 \times P$$

observe radiation on astronomical scales

coherent boost

$$P = \frac{2}{3} \frac{q^2 a^2}{c^3} \gamma^2$$

Very-Long Baseline Interferometry (VLBI)

Combines data from antennas around the world (maximum baselines ~1000 km) to achieve high angular resolution (~milliarcseconds)

Mauna Kea
Hawaii

Owens Valley

Very Long Baseline Array (VLBA)

Tracking Active Galactic Nuclei with Austral Milliarcsecond Interferometry (TANAMI) Array

Example: Event Horizon Telescope (EHT)

1.3 mm Images of the Black Hole M87 in the Andromeda Galaxy (EHT Collab. 2017)

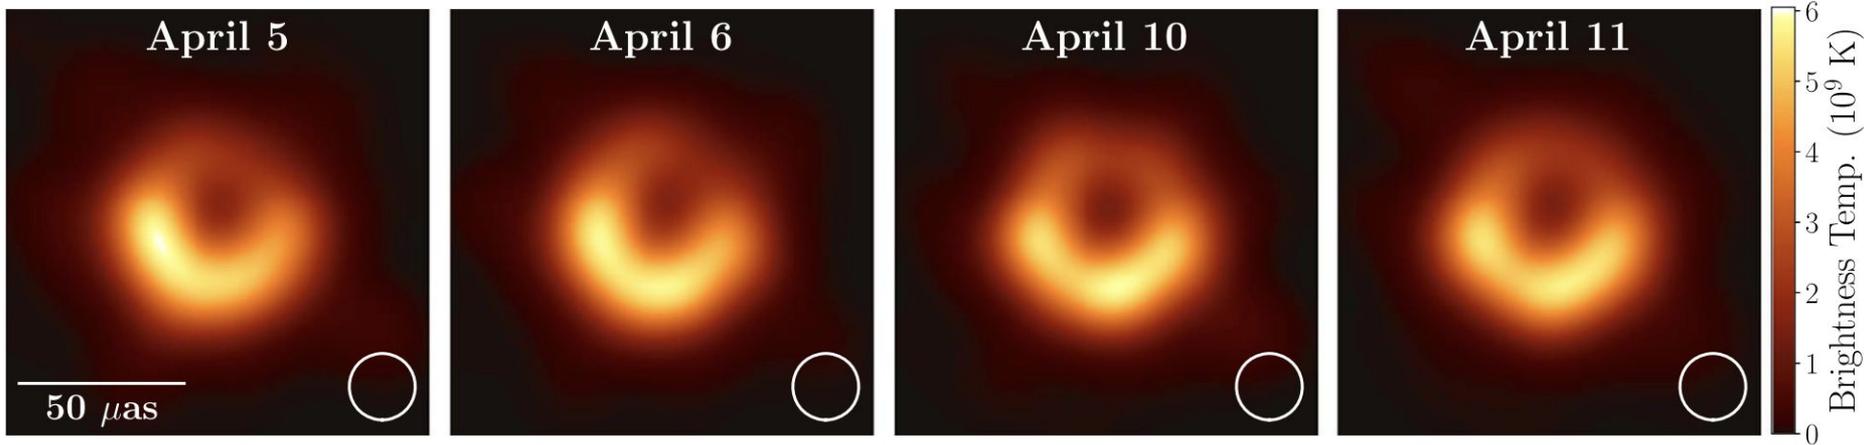

Figure 15. Averages of the three fiducial images of M87 for each of the four observed days after restoring each to an equivalent resolution, as in Figure 14. The indicated beam is $20 \mu\text{s}$ (i.e., that of DIFMAP, which is always the largest of the three individual beams).

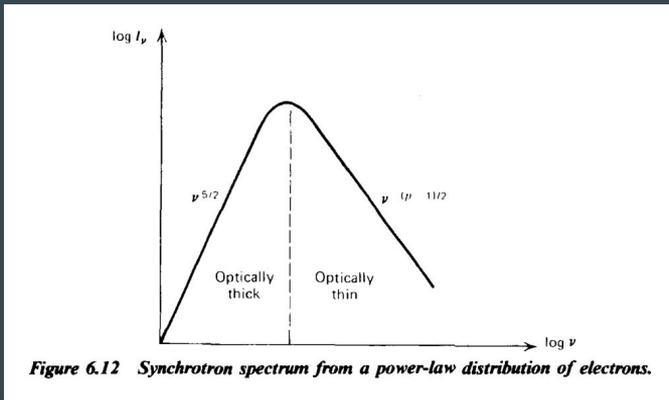

Think-Pair-Share

Compare and contrast the properties of single-dish antennas and interferometers.

Why don't we use interferometry in other areas of astronomy? E.g. why don't we have optical or x-ray interferometers?

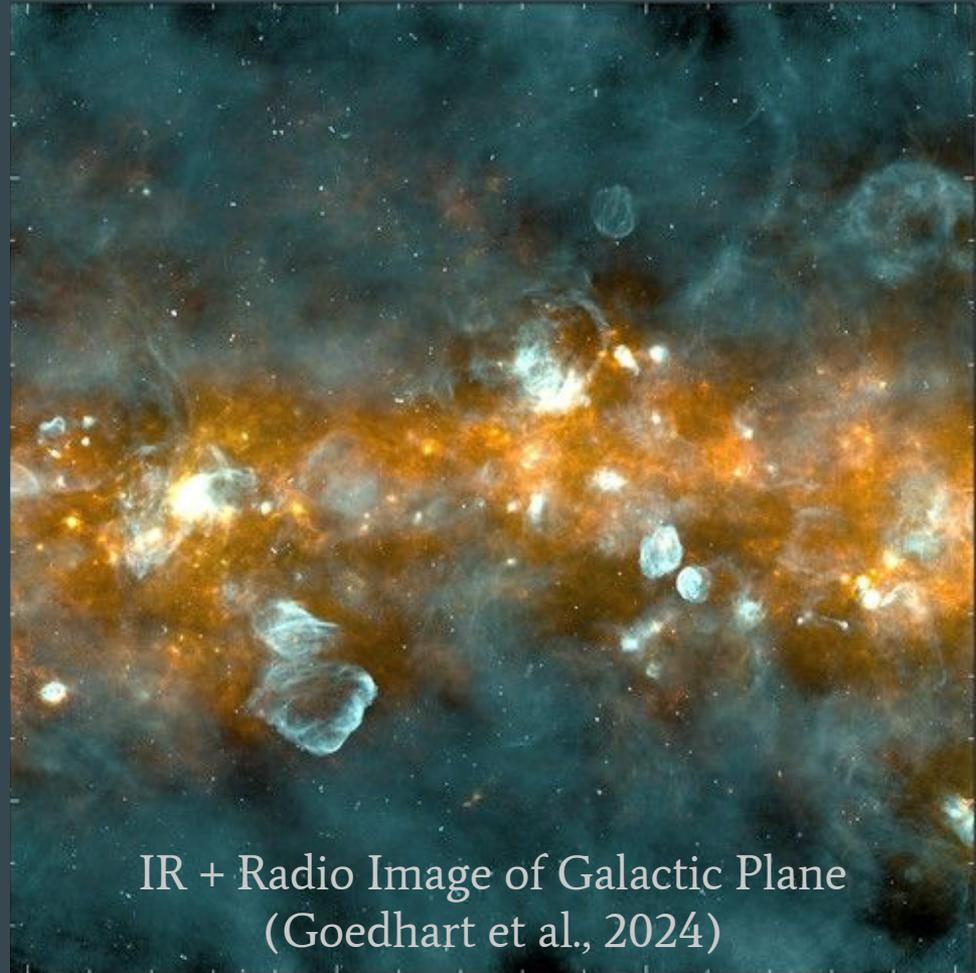

ISM Cyclotron and Synchrotron Radiation

Free electrons moving in the magnetized, ionized ISM produce radiation emission in dense regions

Synchrotron radiation comes from charges moving relativistically

Cyclotron radiation comes from charges moving non-relativistically

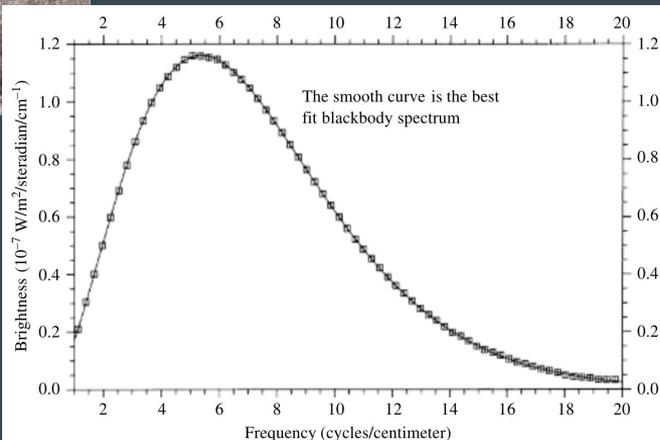

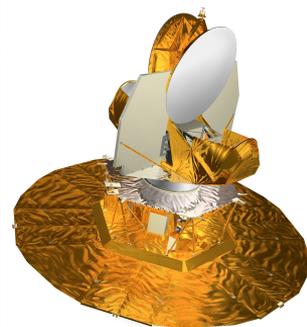

IR + Radio Image of Galactic Plane
(Goedhart et al., 2024)

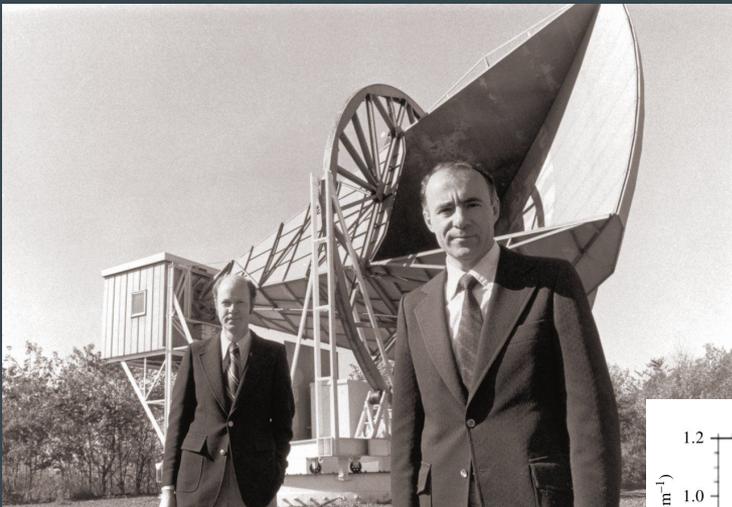

Cosmic Microwave Background (CMB)

2.725 K Blackbody radiation from dense, early universe in thermal equilibrium

The COsmic Background Explorer (COBE), Wilkinson Microwave Anisotropy Probe (WMAP) and the Max Planck Telescope characterized the CMB with Microwave and IR detectors

Arno Penzias and Robert Wilson at the Holmdel Horn Antenna used to detect the noise temperature of the CMB (Penzias & Wilson 1967)

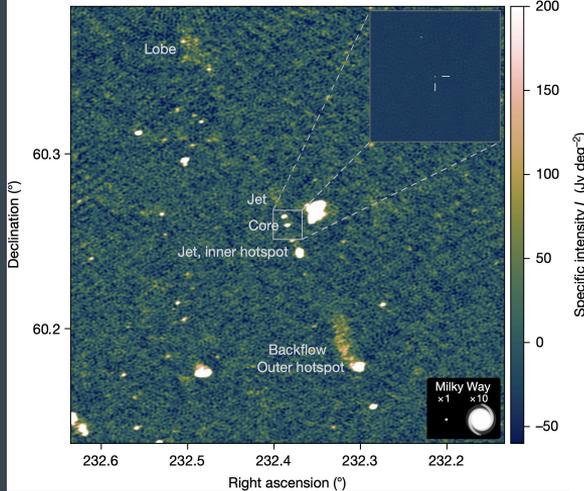

Supermassive Black Hole (SMBH) Jets

Active Galactic Nuclei - Matter falling gravitationally into SMBH at center of galaxy creates a radio-loud **accretion disk**

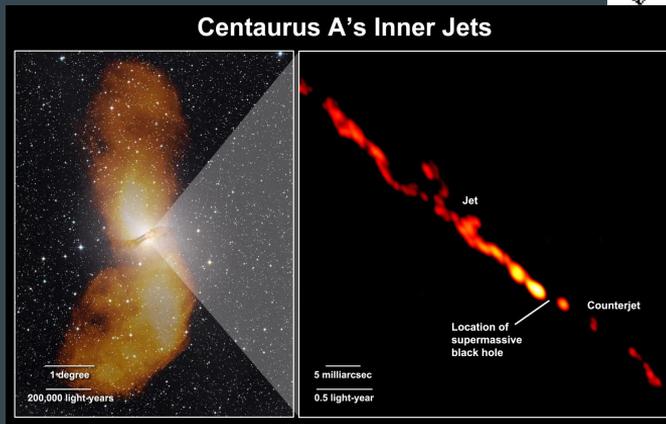

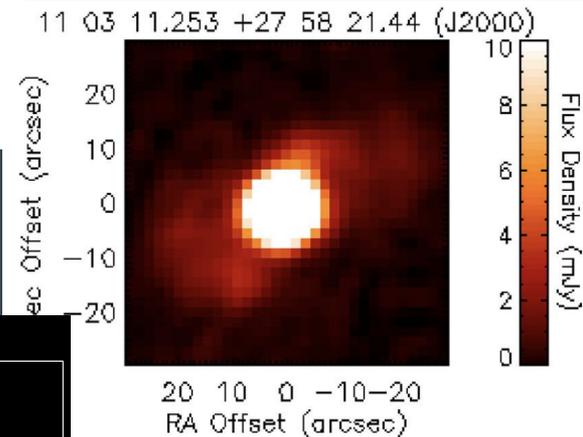

Magnetic field of the black hole can collimate matter into a powerful **jet** of relativistic charges radiating coherently in **radio, X-rays and gamma rays**

Jet can also form turbulent **shocks** with surrounding matter that generates synchrotron emission

Largest Known (7 Mpc) Radio Jet at $\lambda=1.02$ m from the Porphyriion SMBH Detected by the International LOw Frequency ARray (LOFAR) Telescope (ILT; Oei et al., 2024)

VLBA image of an AGN at the center of a spiral galaxy at $\lambda=20$ cm (Kaviraj et al., 2015)

Radio shock fronts (left) and radio jet (right) from SMBH at center of Centaurus A galaxy at 8.4 GHz (Müller et al., 2014)

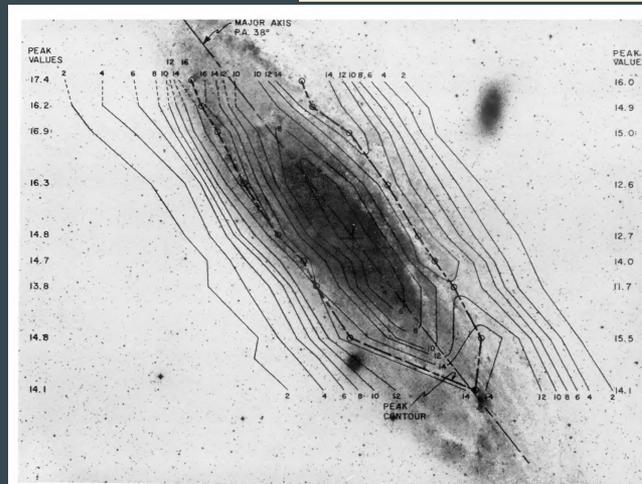

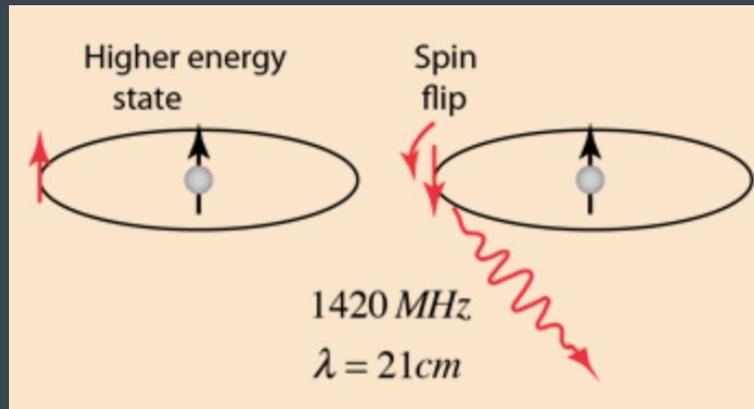

21 cm Hyperfine Hydrogen Spin-Flip Emission Line

Spin: quantum mechanical property of particles

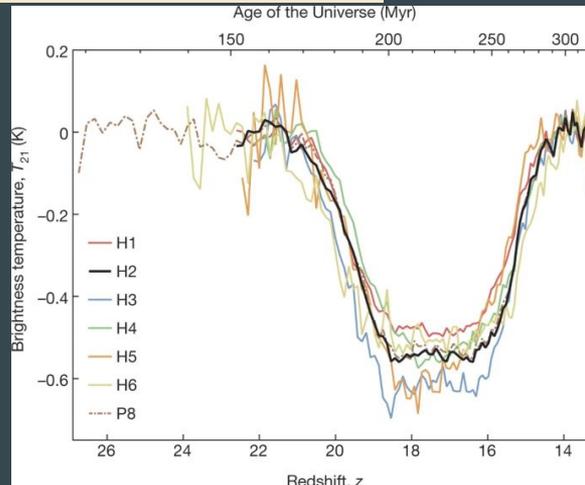

- **fermions** (e.g. electrons, positrons) - spin- $\frac{1}{2}$ particles which can have $s=\pm\frac{1}{2}$
- **bosons** (e.g. protons, neutrons) - spin-1 particles which can have $s=0,\pm 1$

21-cm transition - “hyperfine” transition of Hydrogen electron from $s=+\frac{1}{2}$ to $s=-\frac{1}{2}$

- **Primary tracer of star formation in galaxies**

High-resolution H-I absorption map of the Andromeda Galaxy from the GBT 100-m telescope (Roberts et al., 1966)

Possible detection of 21 cm Hydrogen line from early universe by EDGES Experiment (Bowman et al., 2018)

Think-Pair-Share

We mentioned that white dwarfs, neutron stars, and black holes have 'radio emission'; what do you think that means? Why do we not detect them on our car radios?

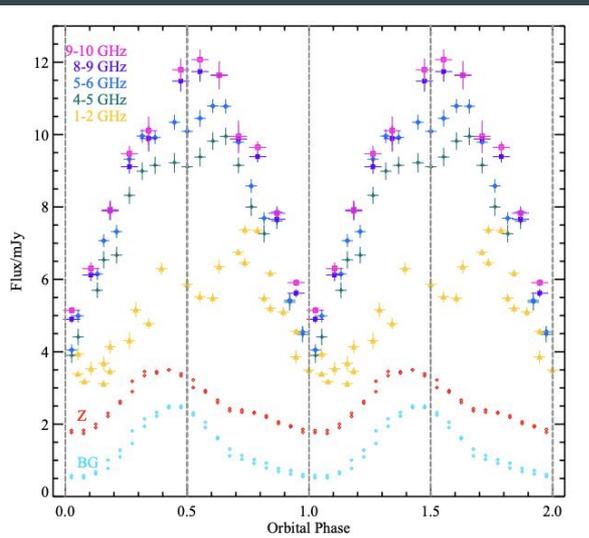

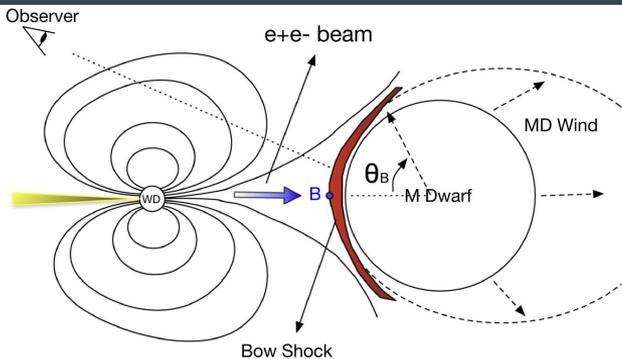

Demo: Let's explore the radio sky!

**What sounds different between the signals we play?
Do pulsars sound different than FRBs? From
magnetars?**

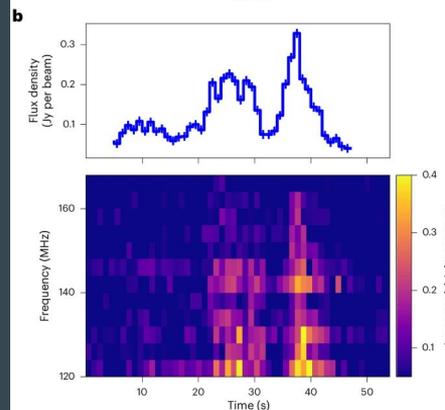

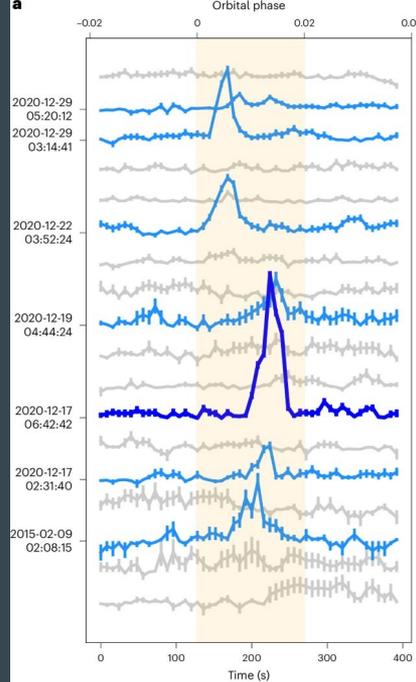

Polars (White Dwarf-M Dwarf Binaries)

Polars are White Dwarf - M Dwarf binaries which produce coherent, periodic radio emission by streaming charged particles between the stars' magnetic poles.

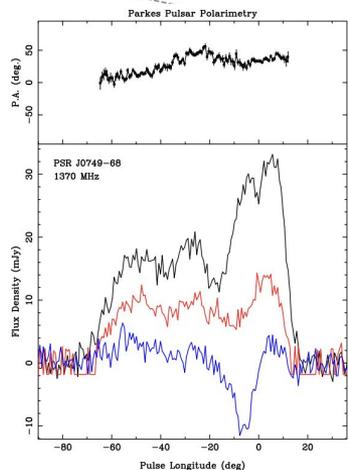

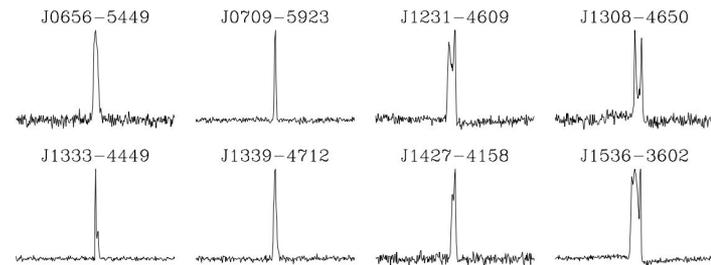

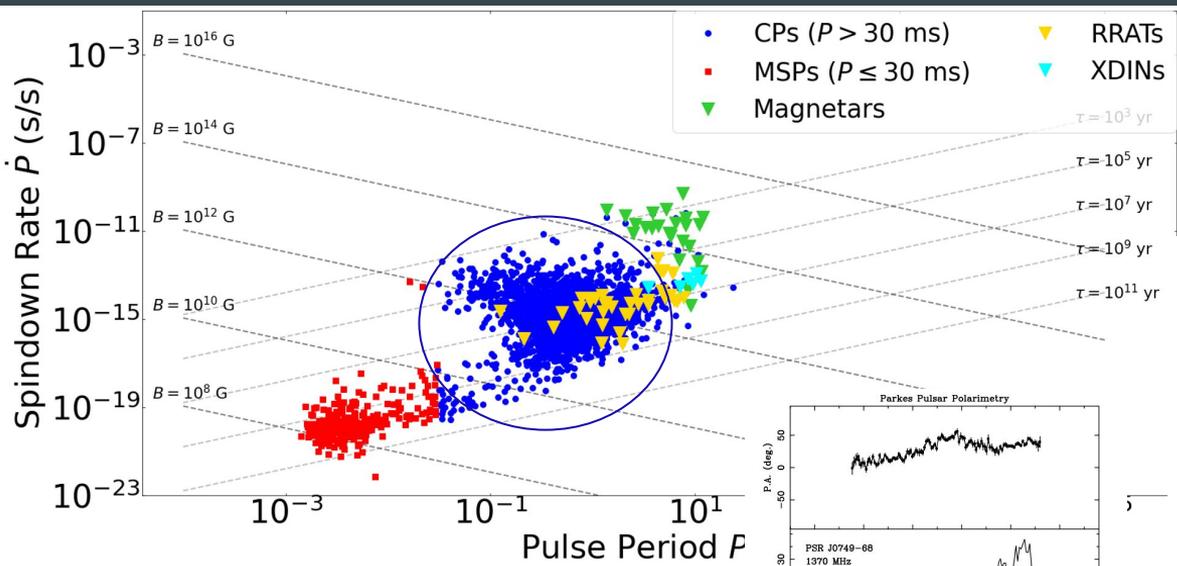

E.g. AR Scorpii produces radio emission at beat frequencies between the 3.6 hour orbital period and 1.95 rotation period (Geng et al., 2016; Stanway et al., 2018)

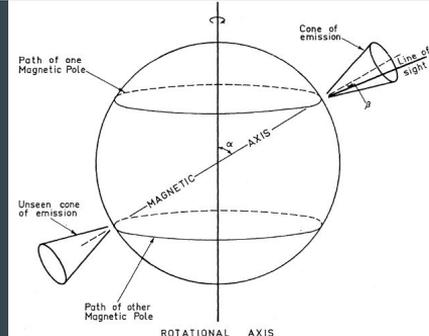

Long Period Radio Transients (LPTs or LPRTs) were discovered in 2022; at least 2 are intermediate polars with hour-scale periods, but are **magnetically locked**. E.g. ILT 1101+5521 has a 2-hour period suspected to be the orbital period (de Ruiter et al., 2025)

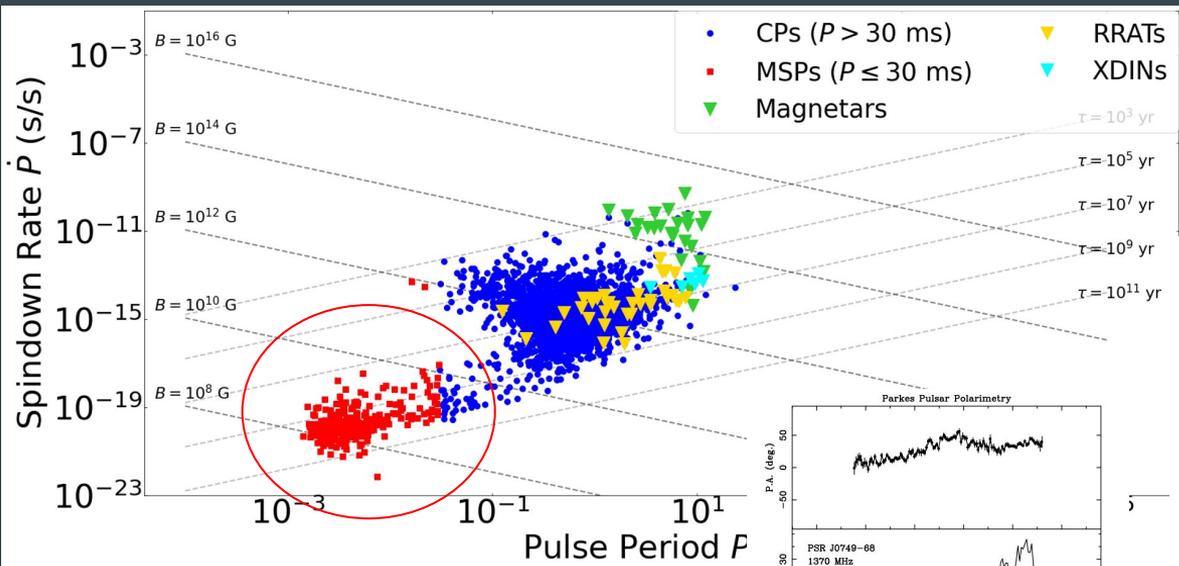

Neutron Stars: Pulsars, Radio Magnetars, RRATs, magnetars

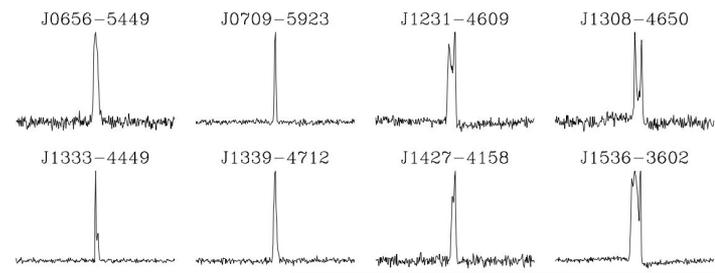

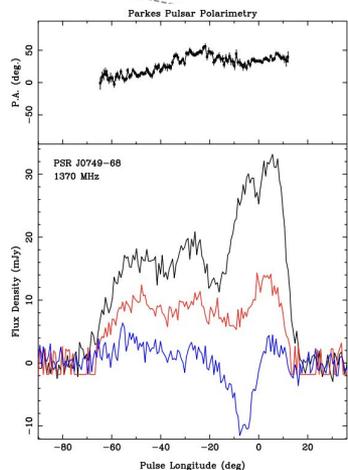

Slow Pulsars
(0.3-10 s): produce coherent radio emission from magnetic poles via charged particle 'avalanche'

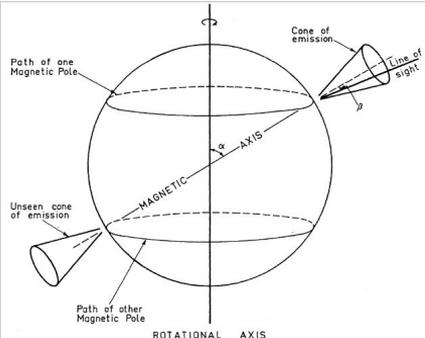

Neutron Stars: Pulsars, Radio Magnetars, RRATs, magnetars

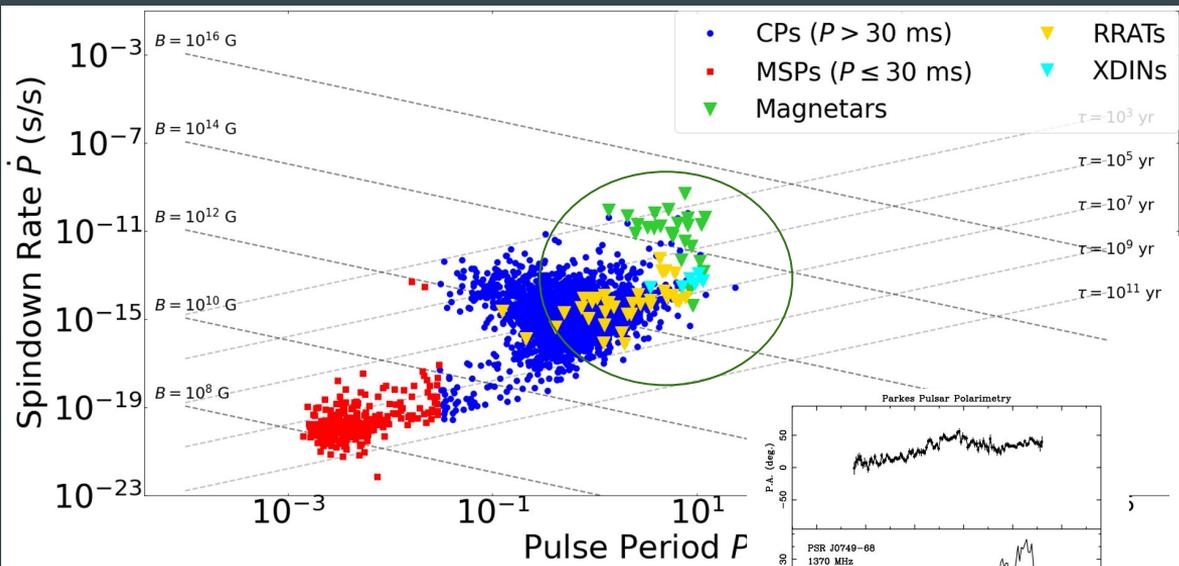

Millisecond Pulsars (<0.3 s):
initially lost their rotational energy,
then accreted from companion to
spin up to millisecond periods

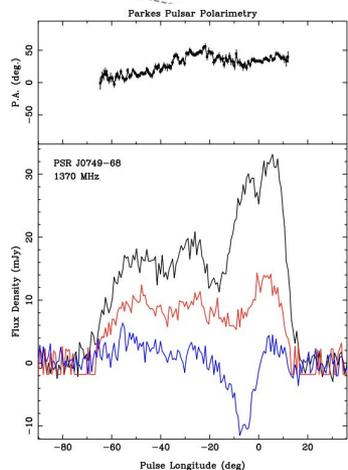

Slow Pulsars (0.3-10 s): produce
coherent radio
emission from
magnetic poles via
charged particle
'avalanche'

Neutron Stars: Pulsars, Radio Magnetars, RRATs, magnetars

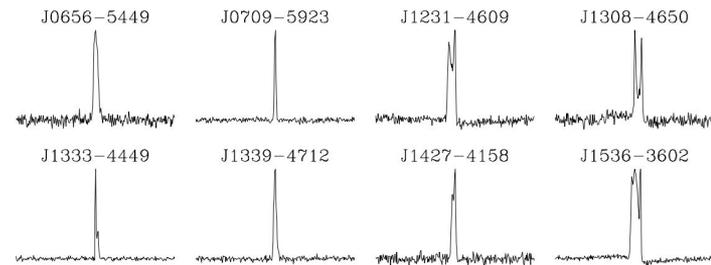

Millisecond Pulsars (<0.3 s):
initially lost their rotational energy,
then accreted from companion to
spin up to millisecond periods

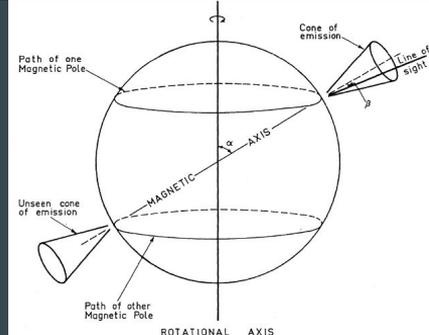

Rotating Radio Transients (RRATs):
only detectable through single pulses
because of irregular nulling

Magnetars (>2s): largest magnetic
fields, produce giant flares and pulses
that exceed rotational energy

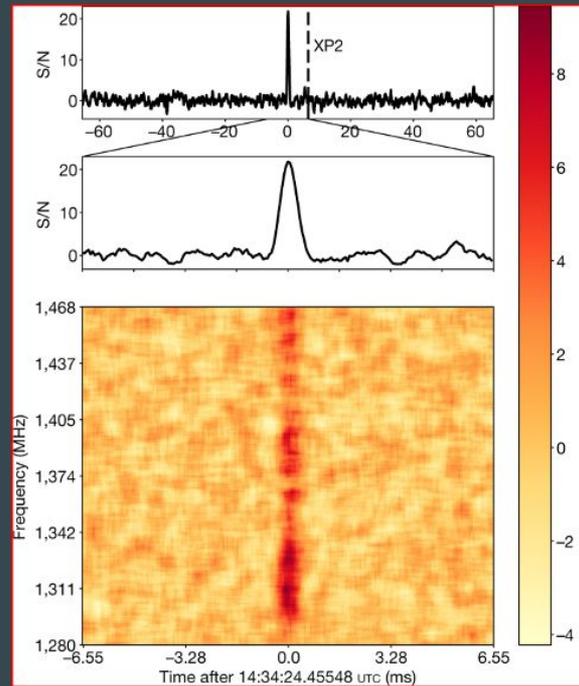

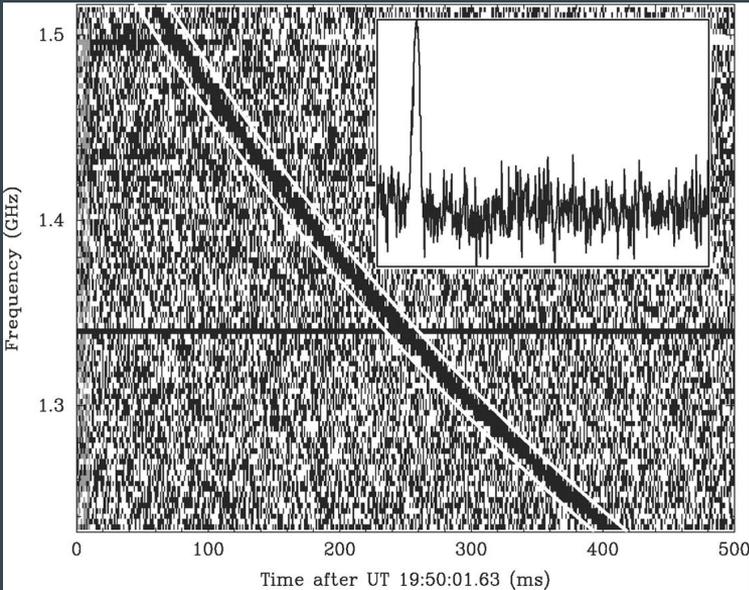

Slow Pulsars (0.3-10 s): produce
coherent radio
emission from
magnetic poles via
charged particle
'avalanche'

Fast Radio Bursts (FRBs)

Extragalactic radio bursts lasting <1ms with unknown source mechanism; leading candidates are magnetars

In 2020, an FRB-like burst was detected from a Galactic magnetar, **SGR J1935+54**, making magnetars the primary candidates (e.g. Bochenek et al., 2020)

First FRB (The Lorimer Burst), detected by the Parkes telescope, was determined extragalactic due to the large frequency-dependent **dispersive delay**

$$I\left(t + \frac{e^2 DM}{2\pi m_e c} (\nu_0^{-2} + \nu^{-2}), \nu\right)$$

At-Home Astronomy: Quick-look Radio Images

Lecture 4: Large-Scale Structure and Cosmology

...

Learning Objectives and Overview

By the end of this course, students will be able to:

...identify major stars and constellations in the night sky, recount the life-cycle of a star from the Main Sequence to supernova, and distinguish between White Dwarfs, Neutron Stars, and Black Holes.

...describe the basic components of an optical telescope, explain the major differences between optical, infrared, and UV astronomy, describe why X-ray and gamma ray telescopes operate differently from OIR and UV telescopes.

...describe the basic components of a radio antenna, explain how radio interferometers work, and list the astrophysical sources of radio waves.

...describe the components of a galaxy (disk, bulge, ISM, halo, CGM), define cosmology, how it is studied (redshift, CMB, 21 cm cosmology, simulations, FRBs), explain how distance, redshift, and time are related within general relativity, and understand how the presence of dark matter and dark energy affect our picture of the Universe.

...list some of the major questions in astronomy today and refer to resources to continue exploring astronomy within and around Pasadena.

Galaxy Morphology

A **Galaxy** is a gravitationally-bound collection of stars, gas, and dust, like our galaxy, the **Milky Way**

Galaxy Luminosity Function

Luminosity Function - number of galaxies with luminosity between $L \rightarrow L+dL$ (distribution)

Schechter Function - originally proposed to be a universal Galaxy Luminosity Function, but now we see it varies with:

- Morphology
- Galaxy density (void, cluster, supercluster)

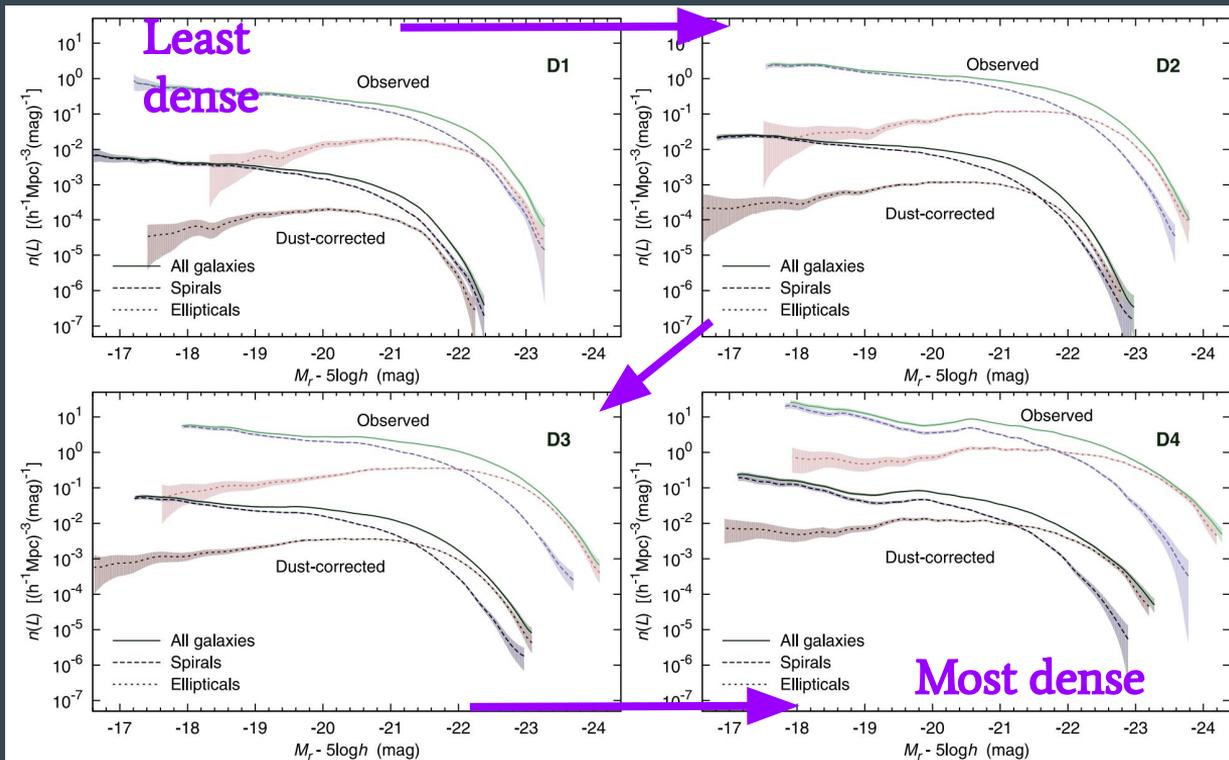

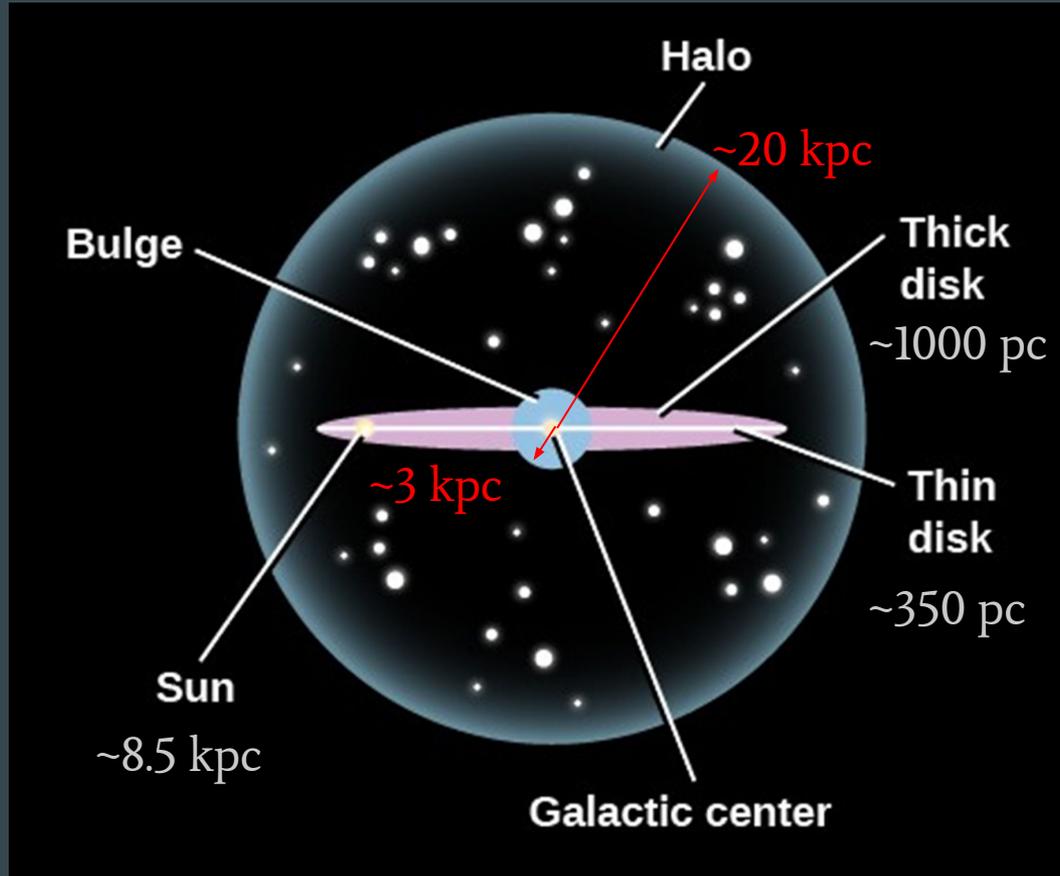

Fig. 13. LFs for different types of galaxies in different environments: *upper left* panel shows the least dense environment (D1) and *bottom right* panel shows the most dense environment (D4). Green solid lines show the LFs for all galaxies; blue dashed lines show the LFs for spiral galaxies; red dotted lines show the LFs for elliptical galaxies. The *upper* LFs in each panel are the observed LFs that are shifted up two units in logarithmic scale and right by one mag. The *lower* LFs in each panel are the attenuation-corrected LFs. Filled areas show the 95% confidence regions. The panels D1 to D4 show different global environmental regions: D1 are void regions and D4 are supercluster regions. The LFs have been normalised to the volume of each sample.

Luminosity functions from Sloan Digital Sky Survey Data
Release 7 (Tempel et al., 2011)

Milky Way Structure

Milky Way Star Formation and Stellar Populations

Population I Stars

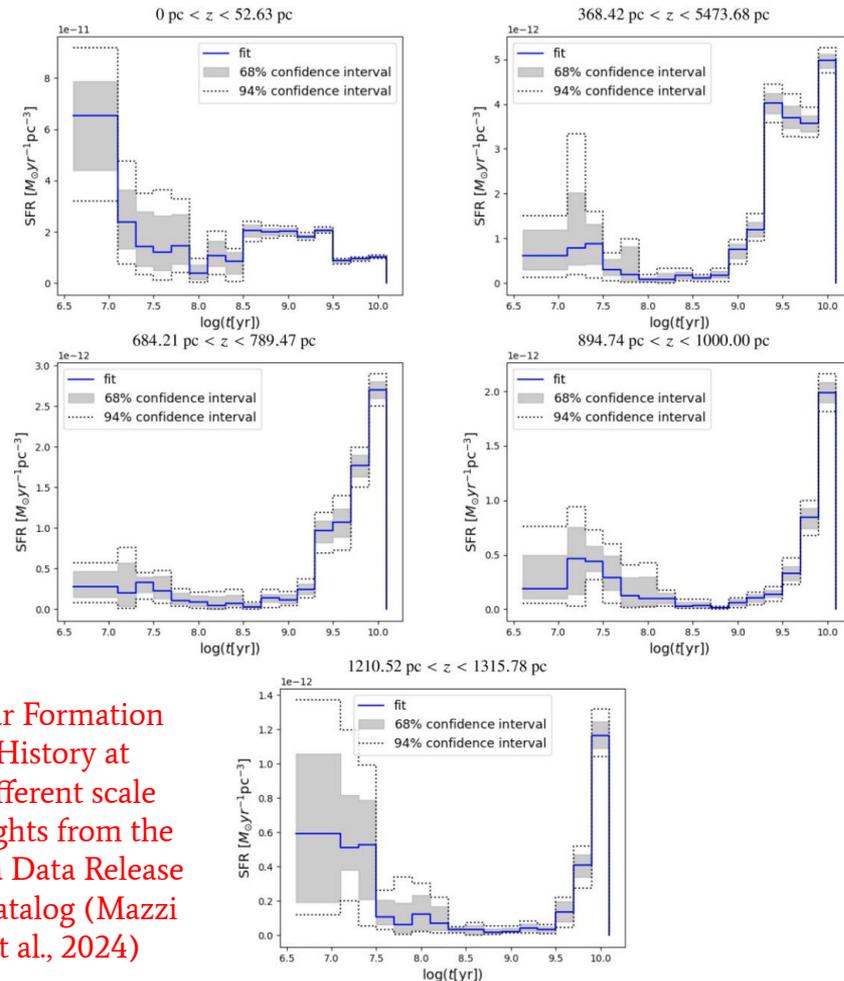

- Metal rich, formed after the explosions of the first stars
- Most in **thin disk**, high fraction of heavy metals (Fe, Si, Ti) → Type Ia SNe, younger
- Some in **bulge**, mostly oxygen, carbon → Type II SNe, older

Population II Stars

- Metal poor, formed from earliest gas in the Galaxy
- Bulge and halo

Population III (?) – theorized to form from primordial gas before galaxies formed

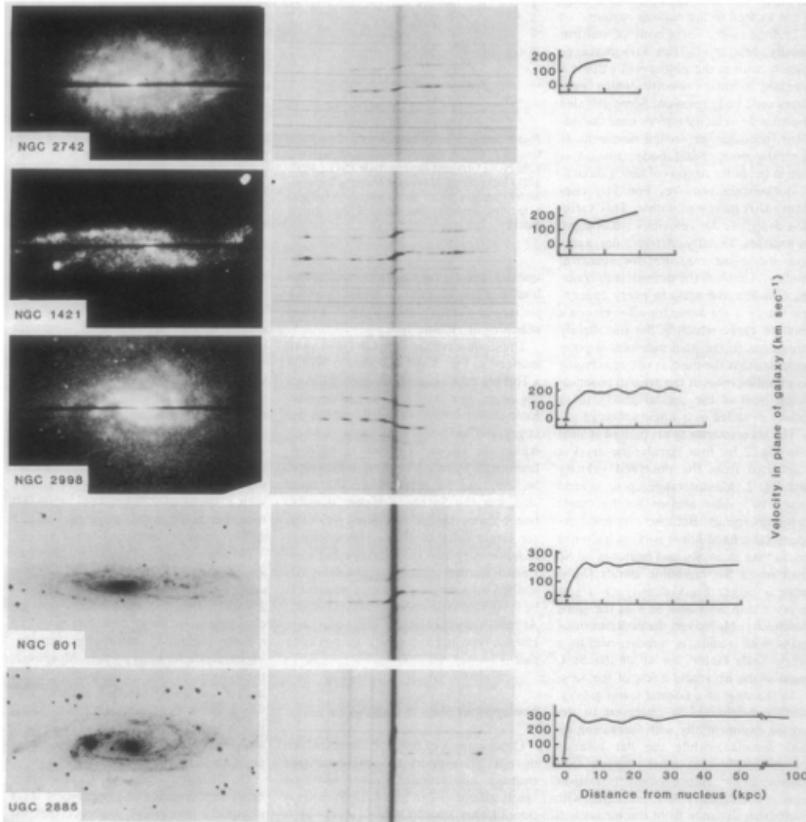

Star Formation History – star formation rate as a function of Galaxy age; remains complex, population model insufficient

Star Formation History at different scale heights from the Gaia Data Release 2 Catalog (Mazzi et al., 2024)

Figure 6. The SFR per unit volume as a function of age determined for the same slices of the sample shown in Fig. 4, also indicated on top of each panel. The blue lines represent the best fitting SFR values, while the grey-shaded areas and the dashed lines mark the 68 and 94 per cent confidence intervals, respectively. We note that the SFR at young ages ($\log(t/\text{yr}) \lesssim 7.5$) is non-zero even at large z , although it is very uncertain.

Missing Matter?

Downloaded from <https://www.science.org at California Institute of Technology on January 19, 2025>

Mounting evidence for large amount of ‘non-luminous’ matter:

- 1933: Fritz Zwicky identified stellar mass of Coma cluster much lower than dynamical mass based on galaxy velocities
- 1940: Jan Oort studies of NGC 3115 dynamics imply mass distribution different than light distribution
- 1945: Martin Schwarzschild finds inconsistent rotation curve of M31
- **1962: Vera Rubin measures flat Milky Way rotation curve from 888 stars, first confirmation of a “Dark Matter Halo”**

Images, spectra, and rotation curves for a sample of galaxies showing flat rotation curves (Rubin et al. 1962, 1983)

Think-Pair-Share

How do you think galaxies formed?

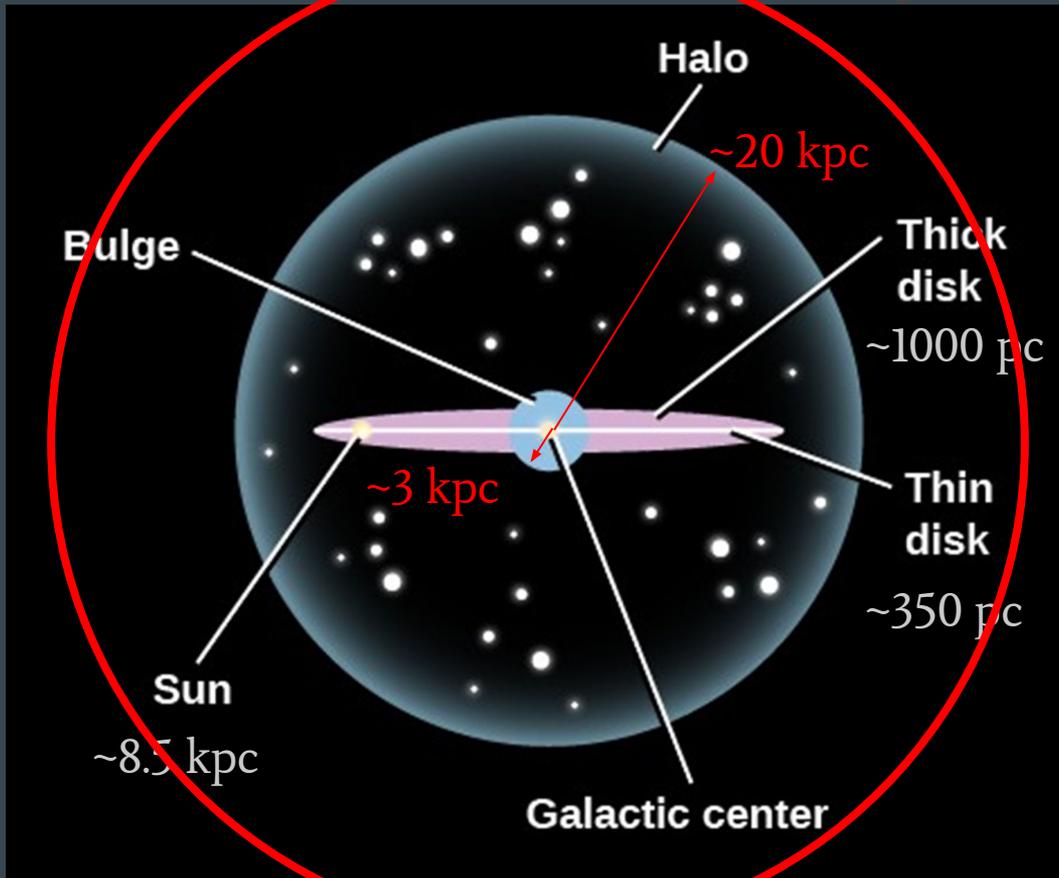

What role do you think dark matter plays in galaxy formation?

Milky Way Structure

Hierarchical (bottom-up) galaxy formation:

[1] Dark matter perturbations ($10^{12}M_{\text{sun}}$) define where galaxies will form → **cosmic web**

[2] Within DM perturbations, first small clusters (10^6M_{sun}) collapse, begin forming stars and globular clusters → **bulge**

Dark Matter Halo
~100 kpc

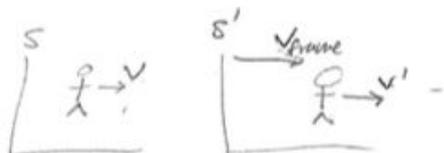

[3] Collisions between small clusters disrupt star formation, collide into larger ($10^{10}M_{\text{sun}}$) proto-galaxies → **stellar halo**

[4] Residual torque from collisions and gravitational interactions induce angular momentum, causes matter to settle into disk → **thick disk**

[5] Cool gas settles into smaller scale height → **thin disk**

4.1) Special Relativity

Newtonian relativity →

$$v' = v - v_{\text{frame}}$$

↳ but what happens if $v = c$, the speed of light?

↳ Newtonian physics breaks down when $v \rightarrow c$

Einstein's Postulates

① Principle of Relativity - laws of physics apply in all inertial reference frames

② Speed of Light in a vacuum is $c = 3 \times 10^8$ m/s in all inertial reference frames

frames: if you're on the train, how long for light to reach the ground?

$$\Delta t = 2d/c$$

Lorentz Factor:

$$\gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}}$$

frame S': if you observe at rest, how long for light to reach the ground?

$$d' = \sqrt{d^2 + (v\Delta t')^2}$$

$$\Delta t' = \frac{2d'}{c} = \frac{2\sqrt{d^2 + (v\Delta t')^2}}{c}$$

$$\frac{c^2 \Delta t'^2}{4} = d^2 + \frac{v^2}{4} \Delta t'^2$$

$$(c^2 - v^2) \Delta t'^2 = 4d^2$$

$$\Delta t' = \frac{2d}{\sqrt{c^2 - v^2}} = \frac{\Delta t}{\sqrt{1 - \frac{v^2}{c^2}}}$$

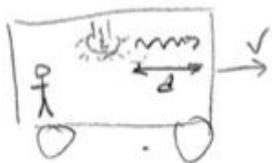

Time Dilation

$$\Delta t' = \gamma \Delta t$$

"moving clocks run slow"

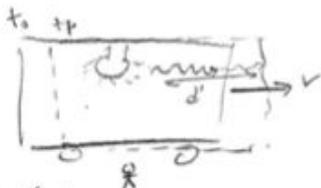

4.2

Ex.

Frame S: how long does it take for light to reach end of the train?

$$\Delta t = \frac{d}{c}$$

Frame S': how long does it take if we observe from the platform?

$$\Delta t' = \frac{d'}{c}$$

$$\frac{d'}{\Delta t'} = \frac{d}{\Delta t} \quad \text{since } c \text{ is the same in both frames}$$

$$d' = d \left(\frac{\Delta t'}{\Delta t} \right) = \gamma d$$

Length contraction

$$d' = \gamma d$$

"lengths measured in moving frames are shorter"

Ex.

Frame S: when does the light hit each side of the train?

$$t_1 = d/c \quad t_2 = d/c$$

$$t = t_1 = t_2 = d/c$$

Frame S': when does the light hit each side of the train?

$$t_1' = \frac{d_1'}{c} = \frac{d' - vt_1'}{c}$$

$$t_2' = \frac{d_2'}{c} = \frac{d' + vt_2'}{c}$$

$$t_1' \left(1 + \frac{v}{c} \right) = \frac{\gamma d}{c}$$

$$t_2' \left(1 - \frac{v}{c} \right) = \frac{\gamma d}{c}$$

$$t_1' = \frac{\gamma}{1 + \frac{v}{c}} t$$

$$t_2' = \frac{\gamma}{1 - \frac{v}{c}} t$$

$$\Rightarrow t_1' = \frac{1 - \frac{v}{c}}{1 + \frac{v}{c}} t_2'$$

Relativity of simultaneity

"events that are simultaneous in one frame are not simultaneous in another"

4.3

Lorentz transformations

- to convert from frame S to frame S'
moving at velocity v relative to S in X direction

$S \rightarrow S'$

$$\begin{aligned} ct' &= \gamma(ct - \beta x) \\ x' &= \gamma(x - \beta ct) \\ y' &= y \\ z' &= z \end{aligned}$$

$S' \rightarrow S$

$$\begin{aligned} ct &= \gamma(ct' + \beta x') \\ x &= \gamma(x' + \beta ct') \\ y &= y' \\ z &= z' \end{aligned}$$

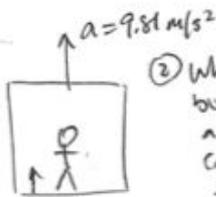

What if frame S' is accelerating?

① Inside box at no windows on the ground

gravity and acceleration are equivalent

... (equivalence principle)

② What if the box is pulled at 9.81 m/s^2 ? Can you tell the difference?

③ What if the box is falling under gravity?

$a = 9.81 \text{ m/s}^2$

Momentum: measurement of an object's inertia ($p = mv$)

- relativistic \Rightarrow use proper velocity measured in rest frame:

$$p = \gamma m v$$

$$\text{Energy} = E = \gamma m c^2 = (pc)^2 + (mc^2)^2$$

- rest energy: for $\gamma = 1$

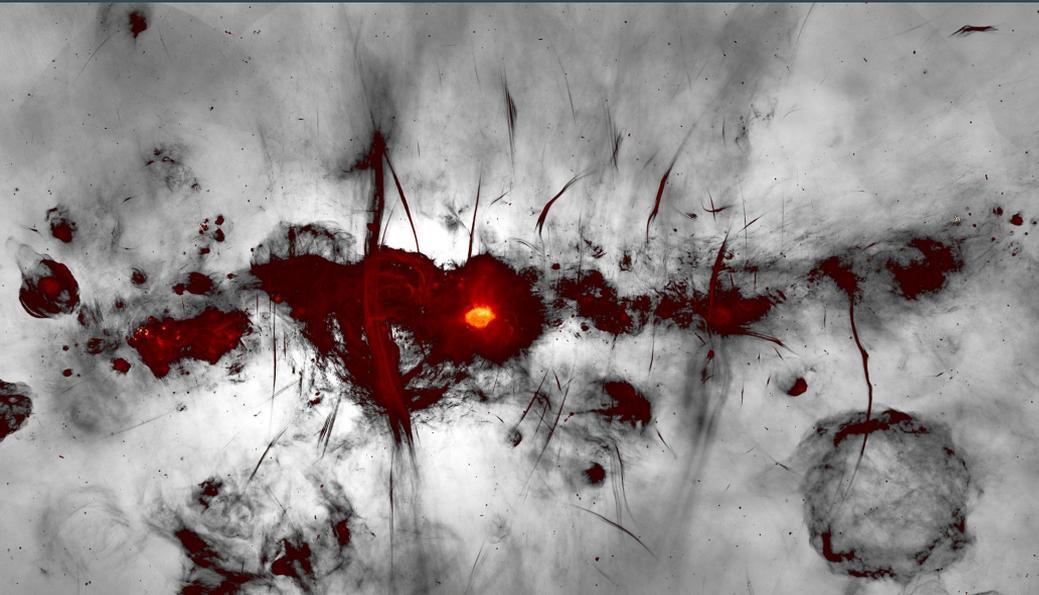

$$E_{\text{rest}} = mc^2$$

Think-Pair-Share

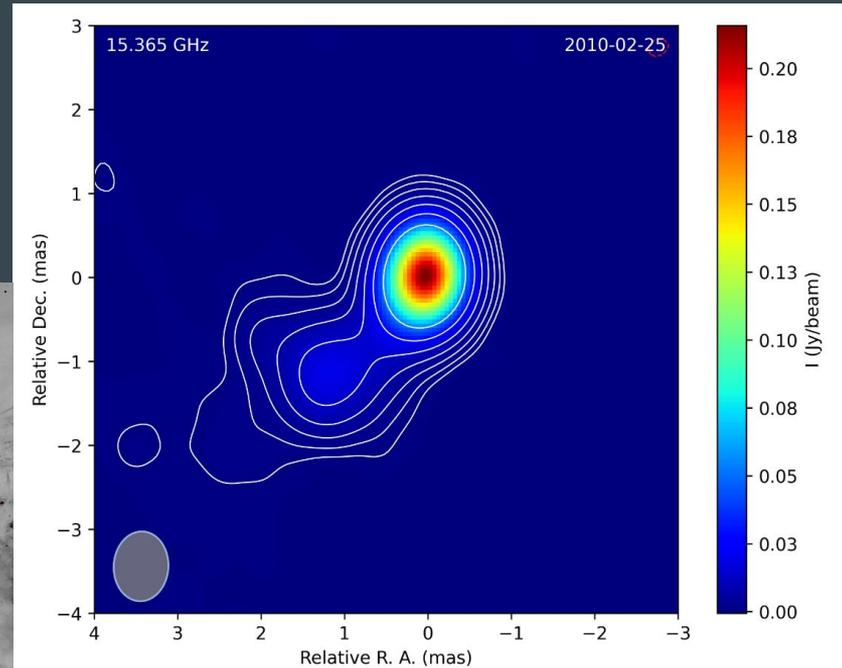

Let's do a thought experiment: say there are two twins who start on earth. If one twin starts travelling very fast, he experiences time passing more slowly than the one on earth. After a long time, he turns around and comes back at the same speed. When he arrives, will he be older, younger, or the same age as his twin?

Why?

Special Relativity in Astronomy

Synchrotron Radiation (MeerKAT

General Relativity - geometric description of spacetime including gravity

- spacetime: x, y, z, ct

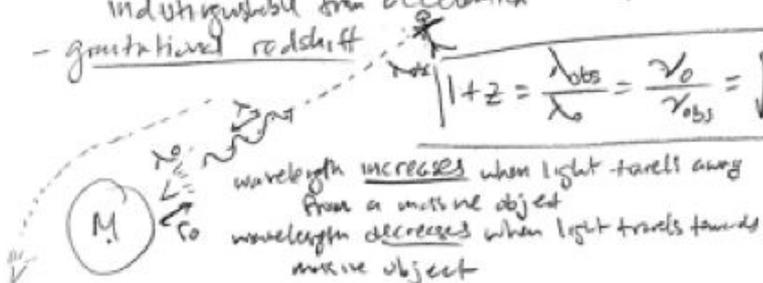

- ① Mass tells spacetime how to curve,
Spacetime tells mass how to move

- geodesic - shortest path between 2 points within a given geometry
- light always follows geodesic, which is curved in curved spacetime

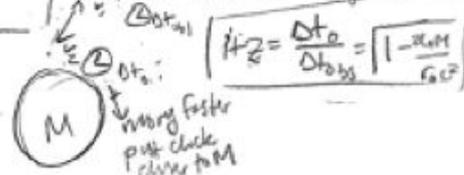

- ② Equivalence Principle - gravitational & inertial mass are the same, i.e. gravity is indistinguishable from acceleration

- gravitational redshift

$$1+z = \frac{\lambda_{obs}}{\lambda_0} = \frac{\gamma_0}{\gamma_{obs}} = \sqrt{\frac{1-\frac{2GM}{r_0c^2}}{1-\frac{2GM}{rc^2}}}$$

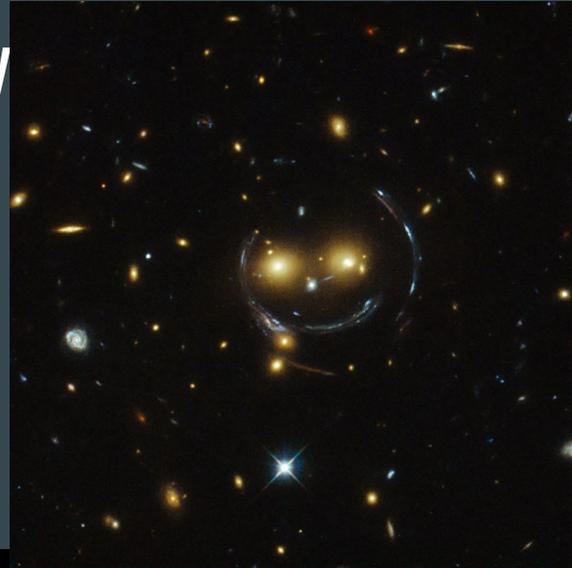

- gravitational time dilation
time runs more slowly near massive objects

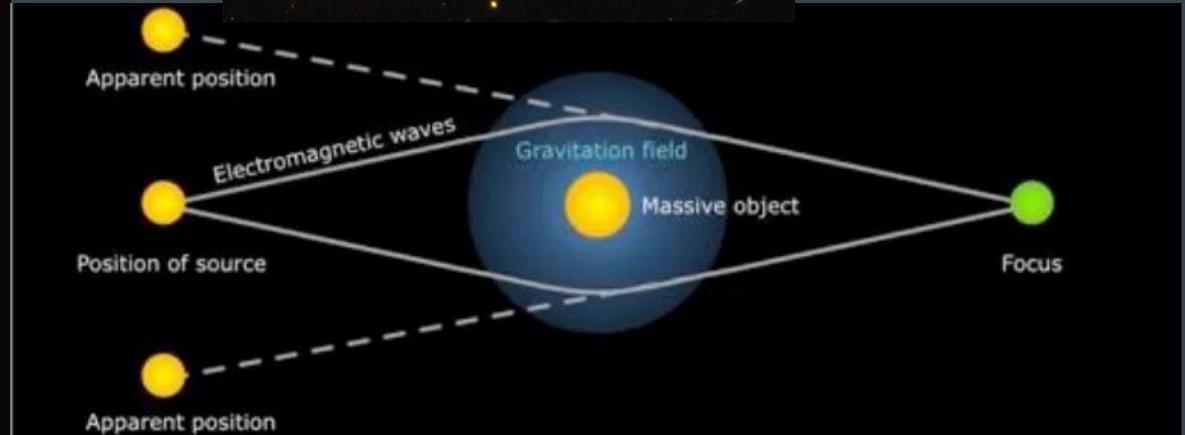

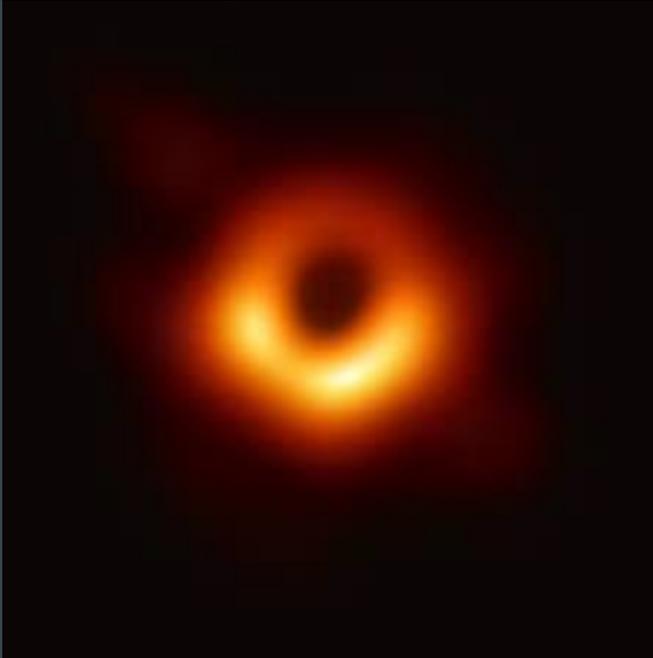

$$1+z = \frac{dt_o}{dt_{obs}} = \sqrt{\frac{1-\frac{2GM}{rc^2}}{1-\frac{2GM}{r_0c^2}}}$$

4.5

Edwin Hubble

↳ observed all spectral lines redshifted \Rightarrow galaxies all moving away from us

↳ more distant galaxies moving away faster: $D_3 > D_2 > D_1$
 $v_3 > v_2 > v_1$

Hubble's law
cosmological redshift: $v_r \approx cz \approx \frac{H_0}{c} D$

← Hubble's constant
 $H_0 \approx 70 \text{ km/s/Mpc}$

- isotropic - universe has no preferred center or direction
 \Rightarrow galaxies are all moving away from each other

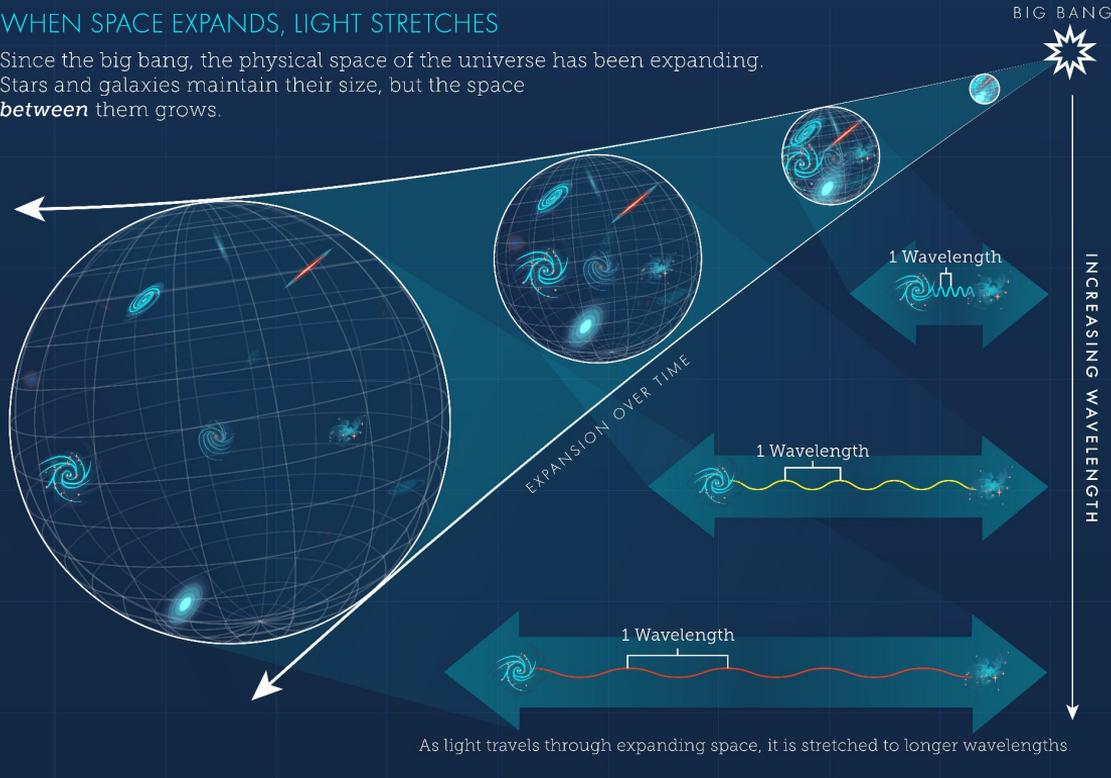

- expansion is accelerating \rightarrow driven by dark energy

The Expanding Universe

WHEN SPACE EXPANDS, LIGHT STRETCHES

Since the big bang, the physical space of the universe has been expanding. Stars and galaxies maintain their size, but the space *between* them grows.
